Northern Shrimp Advisory Panel Meeting

November 10, 2016 10:00 – 11:30 a.m. Portsmouth, New Hampshire

Draft Agenda

The times listed are approximate; the order in which these items will be taken is subject to change; other items may be added as necessary.

| 1. | Welcome/Call to Order (G. Libby) | 10:00 a.m. |
|----|---|------------|
| 2. | Board ConsentApproval of agenda | 10:00 a.m. |
| 3. | Public Comment | 10:05 a.m. |
| 4. | Review 2016 Stock Status Report and Technical Committee Recommendations • Presentation of Stock Status Report (<i>R. Eckert</i>) | 10:15 a.m. |
| 5. | Formulate Advisory Panel Recommendations for 2016/2017 Fishery Specifications (<i>G. Libby</i>) | 10:45 a.m. |
| 6. | Other Business/adjourn | 11:30 a.m. |

Northern Shrimp Section Meeting

November 10, 2016 1:00 – 3:00 p.m. Portsmouth, New Hampshire

Draft Agenda

The times listed are approximate; the order in which these items will be taken is subject to change; other items may be added as necessary.

| 1. | Welcome/Call to Order (D. Abbott) | 1:00 p.m. |
|----|--|-----------|
| 2. | Board ConsentApproval of agenda | 1:00 p.m. |
| 3. | Public Comment | 1:05 p.m. |
| 4. | Review 2016 Stock Status Report and Technical Committee Recommendations • Presentation of Stock Status Report (R. Eckert) | 1:15 p.m. |
| 5. | Review Advisory Panel Recommendations (G. Libby) | 1:45 p.m. |
| 6. | Set 2016/2017 Fishery Specifications (D. Abbott) Final Action | 2:00 p.m. |
| 7. | Other Business/adjourn | 3:00 p.m. |

1050 N. Highland Street. Suite 200A-N. Arlington, VA 22201 703.842.0740 703.842.0741(fax) www.asmfc.org

Vision: Sustainably Managing Atlantic Coastal Fisheries

TRAVEL AUTHORIZATION

TA No. 16-073 Charge To: 0296000INOR Approved by: Laura Leach

Meeting Name: Northern Shrimp Advisory Panel and Section Meeting

Meeting Date: NOV-10-2016

Meeting Location: Urban Forestry Center, Portsmouth, NH

Hotel Details: Meeting Location: Urban Forestry Center, 45 Elwyn Road Portsmouth, New Hampshire 03801

Cutoff Date:

Per Diem: Meals: \$54 (\$13/\$15/\$26)

Mileage Rate: \$0.54/mile; transportation expenses over \$500 must be pre-approved by Laura Leach, Pat

Campfield, Toni Kerns or Mike Cahall

Airport

Transportation:

Local

Transportation:

Basic Guidelines: If the distance from your office to the meeting site is under 35 miles, ASMFC will not reimburse

hotel, mileage or per diem but may reimburse any miscellaneous expenses that would not normally occur during a work day (i.e., parking, tolls). You are responsible for determining your arrival and departure times. Commissioners (or their proxies) are eligible to be at all meetings; all others are eligible for reimbursement for meetings of boards/committees of which they are a member. ASMFC reserves the right to disallow travel expenses it deems excessive or unnecessary to conduct ASMFC business. Complete ASMFC Travel Reimbursement Guidelines can be found at www.asmfc.org/files/Meetings/TravelReimbursementGuidelines_Jan2016.pdf.

Reimbursement: You must submit an ASMFC travel voucher with receipts within 30 days of the final day of

travel. Electronic travel vouchers and scanned receipts are preferred and should be sent to accounting@asmfc.org. Vouchers and receipts will also be accepted via snail mail if emailing is

not an option.

General Notes:

Authorized Travelers:

Abbott, Dennis Adler, William Alexander, Marshall Appelman, Max Armstrong, Mike Bennett, Mark Eastman, Michael Eckert, Robert Ferrara, Sarah Fuller, Spencer Gamage, Arnold Grout, Doug Keliher, Pat Hunter, Maggie Jurek, Joseph Kendall, Peter Kerns, Toni Lang, Andrew Langley, Brian Lee, Stephen Libby, Gary Mckiernan, Dan Peake, Sarah Pierce, David

Seiders, John Stockwell, Terry Testaverde, Joseph

1050 N. Highland Street. Suite 200A-N. Arlington, VA 22201 703.842.0740 703.842.0741(fax) www.asmfc.org

STOCK STATUS REPORT

FOR

GULF OF MAINE NORTHERN SHRIMP — 2016

Prepared
October 27, 2016
By the
Atlantic States Marine Fisheries Commission's
Northern Shrimp Technical Committee

Robert Eckert, Chair (New Hampshire F&G)
Kelly Whitmore (Massachusetts DMF)
Dr. Anne Richards (NMFS NEFSC)
Margaret Hunter (Maine DMR)
Dr. Katie Drew and Max Appelman (ASMFC)

SUMMARY

Landings in the Gulf of Maine northern shrimp fishery since the mid-1980s have fluctuated between 346–9,500 mt, reflecting variations in year class strength as well as regulatory measures, participation, and market conditions in the fishery. Landings in 2013 declined to 346 mt, which was 55% of the TAC set by ASMFC for 2013 (625 mt). The fishery was closed during 2014 – 2016 due to poor resource conditions. Removals in 2014, 2015 and 2016 were 0.3 mt, 6.7 mt, and 13.3 mt, respectively, as part of a cooperative winter sampling program during the moratorium. Catches from the 2016 winter sampling program were primarily of age-3 females (2013 year class).

A benchmark assessment review in 2014 revealed problems with model performance in recent years for Gulf of Maine northern shrimp. The problems were thought to be due primarily to recent extreme fluctuations in abundance. No models were accepted for use in shrimp assessment and management. The current assessment therefore uses an index-based approach to evaluate the condition of the stock. A benchmark assessment which will explore alternative modeling approaches is scheduled for peer-review in 2017.

The index-based assessment approach evaluates a suite of indicators including fishery performance, survey indices of abundance and biomass, and environmental conditions. Abundance and biomass indices for 2012–2016 are the lowest on record of the thirty-three year time series. Recruitment indices for the 2010–2015 year classes are also poor and include the three smallest year classes on record. As a result, the 2012–2016 indices of harvestable biomass are the lowest on record. The recruitment index increased in 2016 but is still well below the stable period mean (13th lowest value on record). Current harvestable biomass is almost entirely composed of the 2013 year class. Recruits from the 2015 and 2016 year classes are not expected to reach exploitable size until 2018 and 2019, respectively.

Recruitment of northern shrimp is related to both spawning biomass and ocean temperatures, with higher spawning biomass and colder temperatures producing stronger recruitment. Ocean temperatures in western Gulf of Maine shrimp habitat have increased over the past decade and reached unprecedented highs within the past several years. While 2014 and 2015 temperatures were cooler, 2016 temperatures were again high, and temperature is predicted to continue rising as a result of climate change. This suggests an increasingly inhospitable environment for northern shrimp and the need for strong conservation efforts to help restore and maintain a fishable stock.

Given the continued poor condition of the resource and poor prospects for the near future, the NSTC recommends that the Northern Shrimp Section extend the moratorium on fishing through 2017.

Introduction

Biological Characteristics

Northern shrimp (Pandalus borealis Krøyer) are hermaphroditic, maturing first as males at about

1½ years of age and then transforming to females at about age 3 in the Gulf of Maine (Haynes and Wigley 1969). Spawning takes place in offshore waters beginning in late July. By early fall, most adult females have extruded their eggs onto the abdomen. Eggbearing females move inshore in late autumn and winter, where the eggs hatch. Juveniles remain in coastal waters for a year or more before migrating to deeper offshore waters, where they mature as males. The exact extent and location of these migrations is variable and somewhat unpredictable. The males pass through a of transitional stages before maturing as females. Some females may survive to repeat the spawning process in succeeding years. The females are the

individuals targeted in the Gulf of Maine fishery.

Fishery Management

The Gulf of Maine Northern Shrimp fishery is managed by the ASMFC Northern Shrimp Section (Section). The management framework evolved during 1972–1979 under the auspices of the State/Federal Fisheries Management Program. In 1980, this program was restructured as the Interstate Fisheries Management Program (ISFMP) of the Atlantic States Marine Fisheries Commission (ASMFC). The Fishery Management Plan (FMP) for Northern Shrimp was first approved under the ISFMP in October 1986 (McInnes 1986, ASMFC 1986).

In 2004, the Section implemented Amendment 1 which established biological reference points for the first time in the northern shrimp fishery and expanded the tools available to manage the fishery. Management of northern shrimp under Amendment 1 resulted in a rebuilt stock and increased fishing opportunities. However, early season closures occurred in the 2010 and 2011 fishing seasons due to landing rates being greater than anticipated, and untimely reporting, resulting in short notice of the season closures and an overharvest of the recommended total allowable catch (TAC).

In 2011, the Section implemented Amendment 2 which completely replaced the FMP. The amendment provided management options to slow catch rates throughout the season, including trip limits, trap limits, and days out of the fishery. The amendment also modifies the fishing mortality reference points to include a threshold level, includes a more timely and

comprehensive reporting system, and allows for the initiation of a limited entry program to be pursued through the adaptive management process.

In November 2012, the Section implemented Addendum I to Amendment 2. The addendum, clarifies the annual specification process, and allocates the annual hard TAC with 87% for the trawl fishery and 13% for the trap fishery based on historical landings by each gear type. Addendum I also implemented a season closure provision designed to close down the northern shrimp fishery when a pre-determined percentage (between 80–95%) of the annual TAC has been projected to be caught. Lastly, the addendum instituted a Research Set Aside (RSA) program which allows the Section to "set aside" a percentage of the annual TAC to help support research on the Northern Shrimp stock and fishery. The Section may set a RSA during years of a moratorium.

Since the implementation of Amendment 2 the Gulf of Maine northern shrimp fishery and population has experienced significant changes. Also, substantial changes in other Northeast fisheries resulted in increased effort in the northern shrimp fishery in 2010 – 2012. This increased fishing pressure, coupled with failed recruitment, the lowest abundance indices on record, and unfavorable environmental conditions have resulted in a highly uncertain future for the resource. To address these uncertainties, the Section initiated development of Amendment 3 in June 2014, which considers management measures to control effort and stabilize the fishery. The Section is expected to consider Draft Amendment 3 for public comment this winter of 2017.

Biological Reference Points

| Biological Reference Points Defined in Amendment 2 | | | | | | | | | |
|--|----------|--|--|--|--|--|--|--|--|
| Reference Point | Value | Definition | | | | | | | |
| F _{target} | 0.29 | Average fishing mortality rate during 1985 to 1994 when biomass and landings were "stable" | | | | | | | |
| F _{threshold} | 0.37 | F_{1987} = maximum annual F during the same stable period (1985–94) | | | | | | | |
| F _{limit} | 0.60 | Value that was exceeded in the early to mid-1970s and in the mid-1990s when the stock collapsed | | | | | | | |
| B _{threshold} | 9,000 mt | Based on historical abundance estimates and response to | | | | | | | |
| B _{limit} | 6,000 mt | fishing pressure. B_{limit} set at 2,000 mt higher than the lowest observed biomass at that time. | | | | | | | |

Fishing mortality (F) and biomass (B) reference points described in Amendment 2 are presented in the table above. F reference points were re-estimated by the NSTC in 2013 as $F_{target} = 0.38$ and $F_{threshold} = 0.48$. F_{limit} was not re-estimated within the assessment framework. The F reference points were estimated under the assumption of natural mortality (M) = 0.25, as specified in Amendment 2. Higher values of M are considered more realistic (e.g. M = 0.5); however using a higher constant value for M does not generally alter conclusions about stock status because the increased M scales the entire assessment. Overfishing is occurring if the $F_{threshold}$ is exceeded.

Amendment 2 does not specify a biomass target because the Section did not want to set unlikely goals for a species whose productivity is sensitive to environmental conditions. The Section stresses that the threshold is not a substitute for a target. The Section will manage the fishery to maintain stock biomass above the threshold. Furthermore, the Section's management decisions will be affected by the year class composition of the stock.

Annual Fishery Specifications Process

The process for setting fishery specifications under Amendment 2 is as follows: The NSTC annually reviews the best available data including commercial landings, stock status and survey indices, assessment modeling, etc., and recommends an annual total allowable catch (TAC) to maintain healthy stock status relative to peer reviewed biological reference points. The Section meets annually during a public meeting in the fall to review the Advisory Panel and NSTC's recommendations, set a target TAC, and specify any combination of management measures outlined in Section 4.1 of Amendment 2 through a majority vote. Refer to Appendix 1 for NSTC recommendations and subsequent management action by year from 1986 – 2016.

2014 Benchmark Assessment Review

A set of three stock assessment models for northern shrimp were presented to the Northeast Fisheries Science Center's Stock Assessment Workshop (SAW) for review as part of the most recent benchmark assessment (NEFSC 2014). Several important conclusions came from the peer review panel. These are summarized below (the reviewers' reports can be accessed at http://www.nefsc.noaa.gov/saw/saw58/index.html.):

- Despite the high quality data available for northern shrimp, the models have difficulty fitting
 the data because of extreme fluctuations in recent years, including the exceptionally high
 2006 shrimp survey index, and the sudden decline of all indices in 2012 followed by sustained
 extreme lows.
- A new statistical framework was developed for the catch-survey analysis (CSA, Collie and Sissenwine 1983; Cadrin et al. 1999). CSA has been used to guide management decisions in the shrimp fishery since 1997. The review panel considered the new statistical framework an important advance, but felt the results were overly sensitive to weightings chosen for different components of the model (e.g. catch data, survey data), and on this basis rejected the new CSA for management use. They were not able to comment on the applicability of the previously-accepted version of CSA because there was insufficient time to review the previous version.
- The review panel concluded that a new length-based model developed for northern shrimp has promise but needs further development and testing before application to management.
- The review panel agreed that the use of a surplus production model (ASPIC) as a confirmatory
 analysis should be discontinued. ASPIC is unable to adequately handle the large fluctuations
 in recruitment which are typical of northern shrimp population dynamics.

In light of the review panel's comments on the new version of CSA, the NSTC conducted exploratory work to evaluate whether the previous CSA version had similar issues (these issues

could not have been detected under the previous statistical framework). The results of the exploratory analysis suggest that the previous CSA also had difficulty with the major swings in data in recent years, although the conclusions with respect to overfishing status were robust and did not differ with different weighting scenarios.

Given the results of the benchmark assessment review and exploratory CSA analysis, the NSTC is not presenting modeling results in this stock assessment. Instead, stock status is evaluated using an index-based approach.

Management in the 2014 – 2016 Fishing Seasons

Following the 2013 stock status report, the Northern Shrimp Section imposed a moratorium on the fishery for the 2014 season. The Section considered several factors prior to closing the fishery in 2014. Northern shrimp abundance in the western Gulf of Maine had declined steadily since 2006. The 2012 and 2013 survey indices of total biomass and spawning stock biomass were the lowest on record. Additionally, the stock experienced failed recruitment for three consecutive years prior to 2014 (2010–2012 year classes). The 2014 and 2015 stock status reports indicated continued poor trends in biomass, recruitment, and environmental indices which prompted the Section to extend the moratorium through 2015, and again through 2016. Winter sampling via selected commercial shrimp vessels occurred in 2014, 2015, and 2016 to continue the time series of biological samples that had been obtained from the Gulf of Maine northern shrimp fishery during the fishery moratorium.

COMMERCIAL FISHERY TRENDS

Most northern shrimp fishing in the Gulf of Maine is conducted by otter trawls, although traps are also employed off the central Maine coast. According to federal and state of Maine vessel trip reports (VTRs), trappers averaged 12% of Maine's landings during 2001 to 2007, 18% during 2008 to 2011, and 9% in 2012 (Table 4). Otter trawling effort has accounted for between 78% and 96% of Maine's landings during 2000 to 2013. Harvester reports indicate that trappers accounted for about 7% of Maine's landings in 2013, the lowest since 2004 (4%).

Landings, 1969-2013

Annual landings of Gulf of Maine northern shrimp declined from an average of 11,400 metric tons (mt) during 1969–1972 to about 400 mt in 1977, culminating in a closure of the fishery in 1978 (Table 1, Table 3 and Figure 1). The fishery reopened in 1979 and landings increased steadily to over 5,000 mt by 1987. Landings ranged from 2,100 to 6,500 mt during 1988–1995, and then rose dramatically to 9,500 mt in 1996, the highest since 1973. Landings declined to an average of 2,000 mt for 1999–2001, and dropped further in the 25-day 2002 season to 450 mt, at the time, the lowest northern shrimp landings since the fishery was closed in 1978. Landings then increased steadily, averaging 2,100 mt during the 2003 to 2006 seasons, then jumping to 4,900 mt in 2007 and 5,000 mt in 2008. In 2009, 2,500 mt were landed during a season that was thought to be market-limited. The proposed 180-day season for 2010 was cut short to 156 days with 6,263 mt landed, due to the industry exceeding the total allowable catch (TAC) for that year, and concerns about catching small shrimp.

As in 2010, the 2011 season was closed early due to landings in excess of the TAC. A total of 6,397 mt of shrimp were landed, exceeding the recommended TAC of 4,000 mt by approximately 2,400 mt (Table 1 and Figure 1). The average price per pound was \$0.75 and the estimated landed value of the catch was \$10.6 million (Table 2). In 2012, the season was further restricted by having trawlers begin on January 2 with three landings days per week and trappers begin on February 1 with a 1,000 pound limit per vessel per day. The TAC was set at 2,000 mt (later increased to 2,211 mt on January 20th) and would close when the projected landings reached 95%. The season was closed on February 17; trawlers had a 21-day season and trappers had a 17-day season. Landings for 2012 were 2,485 mt and the average price per pound was \$0.95 with an estimated landing value of \$5.2 million. In 2013, the TAC was set at 625 mt (with 5.44 mt set aside for research tows) and would close when the projected landings reached 85% of the TAC in each fishery (trap and trawl). The trawl fishery was allocated a 539.02 mt TAC and the trap fishery was allocated an 80.54 mt TAC. Trawlers fished for 54 days and trappers fished 62 days culminating in 345.5 mt landed, which is 280 mt under the TAC. The average price per pound was \$1.81 and is the highest observed since 1989 (inflation-adjusted values, Table 2) with an estimated value of \$1,375,788.

Cooperative Winter Sampling/Research Set Aside Program, 2014–2016

In the absence of a commercial fishery in 2014, the State of Maine contracted with a commercial shrimp trawler to collect northern shrimp samples during January – March near Pemaquid Point, in midcoast Maine, chosen as best representing the spatial "center" of a typical winter Maine shrimp fishery (Hunter 2014). No shrimp were landed during the 2014 cooperative winter sampling program, except the collected samples. In 2015, the sampling program was expanded; four trawlers and five trappers collected northern shrimp samples in the Gulf of Maine during January – March under the research set aside (RSA) program implemented through Addendum II to Amendment 2 (Whitmore et al. 2015). The traditional spatial range of the trawl fishery was divided into four regions: Massachusetts-New Hampshire, Western Maine (Kittery to Phippsburg), Midcoast Maine (Phippsburg to Rockland), and Eastern Maine (Vinalhaven to Lubec). In 2016, also under the RSA provision, four trawlers and two trappers collected northern shrimp samples in the Gulf of Maine during January – April (Hunter 2016). The traditional spatial range of the trawl fishery was divided into four regions: Massachusetts-New Hampshire, Western Maine (Kittery to Phippsburg), Midcoast Maine (Phippsburg to Monhegan Island), and Eastern Maine (east of Monhegan Island). During 2015 and 2016, one trawl captain from the qualified applicants was picked at random for each of the four sampling regions. Each trawler fished about once every two weeks, conducting at least three tows per trip, and made no more than five trips. Also, in 2015, four trappers were selected from Midcoast and Eastern Maine and each fished ten traps, tended as often as needed. In 2016, two trappers were selected from midcoast Maine and each fished forty traps, tended as often as needed. In the 2015 RSA fishery, about 6.7 mt were landed. In the 2016 RSA fishery, about 13.3 mt were landed.

Size, Sex, and Maturity Stage Composition of Landings

Size and sex-stage composition data have been collected from port samples of fishery landings from each of the three states. One-kilogram samples were collected from randomly selected landings. Data were expanded from the sample to the vessel's landings, and then from all

sampled landings to total landings for each gear type, state, and month. Size composition data (Figure 2 and Figure 3) indicate that trends in landings have been determined primarily by recruitment of strong (dominant) year classes.

Landings more than tripled with recruitment to the fishery of a strong assumed 1982 year class in 1985–1987 and then declined sharply in 1988. A strong 1987 year class was a major contributor to the 1990–1992 fisheries. A strong 1992 year class, supplemented by a moderate 1993 year class, partially supported large annual landings in 1995–1998. Low landings in 1999–2003 were due in part to poor 1994, 1995, 1997, 1998, and 2000 year classes with only moderate 1996 and 1999 year classes. A very strong 2001 year class supported higher landings in 2004–2006. In the 2007 fishery, landings mostly comprised assumed 4-year-old females from the moderate to strong 2003 year class, and possibly 6-year olds from the 2001 year class. Landings in 2008 were mostly composed of the assumed 4-year-old females from the strong 2004 year class, and the 2003 year class (assumed 5-year-old females, which first appeared as a moderate year class in the 2004 survey).

In the 2009 fishery, landings comprised mainly of assumed 5-year-old females from the strong 2004 year class. Catches in the 2010 fishery consisted of assumed 5-year-old females from the 2005 year class and possibly some 4-year-old females from the weak 2006 year class. The 2011 fishery consisted mainly of 4-year-old females from the assumed 2007 year class. Numbers of 5-year-old shrimp were limited likely due to the weak 2006 year class. Transitional stage shrimp and female stage Is from the 2008 year class, and some males and juveniles from the assumed 2009 year class were observed in 2011, especially in the Massachusetts and New Hampshire landings and Maine's December and January trawl landings. Trawl landings in the 2012 fishery were likely 4-year olds from the moderate 2008 year class, but they were small for their age. Low percentages of males and juveniles were caught in 2012 likely due to the later start date of January 2. In the 2013 fishery, landings were limited but likely comprised 4- and 5-year olds from the moderate 2009 and 2008 year classes that were small for their assumed age. Limited numbers of males and transitionals were observed in landings.

Samples from the cooperative winter sampling program in 2014 comprised of assumed 5-year-old shrimp from the 2009 year class and some small males assumed to be from the fast-growing 2013 year class. Samples from the 2015 RSA program (Figure 2) exhibited an unusually high percentage of small ovigerous females, likely early-maturing and fast-growing females from the 2013 year class. The small females were more prevalent in the Maine trawl samples than in the trap samples or the Massachusetts trawl samples. Some larger females from the assumed 2010 year class were also evident in all samples. Samples from the 2016 RSA program confirmed that members of the 2013 year class were ovigerous (at only three years old) and available inshore, and represented a greater proportion of the catch than older year classes (2010-2012). Some 2016 samples, particularly those from the New Hampshire boat, contained a portion of very large females, possibly from the assumed 2010 year class.

Spatial and temporal differences in the timing of the egg-hatch can be estimated by noting the proportion of mature females (Female II) that have hatched their brood during the season and

across geographic locations. In 2016, similar to 2015, most of the female shrimp were still carrying eggs in late January and early February, and most had hatched off their eggs by the middle of March (Figure 2). The mid-point of the hatch period was estimated to have been February 23 in New Hampshire, March 7 in western Maine, March 15 in midcoast Maine, and March 11 in eastern Maine. Compared to the longer time series of hatch timing estimates (Figure 19), it appears that hatch metrics in 2014-2016 were similar to pre-2000 fisheries, when the hatch started later and the duration of the hatch period was shorter. Egg hatch trends observed in the 2016 winter sampling were consistent with historical regional trends of hatch beginning and ending earlier in the western Gulf of Maine and later in the eastern Gulf of Maine.

Discards

Discard rates of northern shrimp in the northern shrimp fishery are thought to be near zero because no size limits are in effect and most fishing effort occurs in areas where only the larger females are present. Data from a study which sampled the northern shrimp trap fishery indicated overall discard/kept ratios (kg) for northern shrimp of 0.2% in 2010 and 0.1% in 2011 (Moffett et al. 2012). Sea sampling data from Gulf of Maine shrimp trawlers in the 1990s indicated no discarding of northern shrimp (Richards and Hendrickson 2006). On an anecdotal level, port samplers in Maine reported seeing manual shakers (used to separate the small shrimp) on a few trawl vessels during April 2010, but made no similar observations in 2011 through 2013. Discarding of northern shrimp in other Gulf of Maine fisheries is rare (on average less than 0.001% during 2000–2013; Northeast Fishery Observer Program data, NMFS). For these reasons and because detailed data for estimating potential discards are lacking, shrimp discards from the shrimp and other fisheries are assumed zero in this northern shrimp stock status report. However in 2014, aside from the 2-kg samples that were provided to Maine DMR for analysis, all catches (0.3 mt) from the cooperative winter sampling program were discarded at sea.

Black Gill Syndrome

Shrimp collected during routine port-sampling in Maine in 2003 exhibited a high incidence (greater than 70%) of Black Gill Syndrome, also called Black Gill Disease or Black Spot Syndrome. Affected shrimp displayed melanized, or blackened gills, with inflammation, necrosis, and significant loss of gill filaments. Black Gill Syndrome was also documented in the Gulf of Maine in 1966 (Apollonio and Dunton, 1969; Rinaldo and Yevich, 1974). Its etiology is unknown, although fungal and ciliated protist parasites have been implicated. In samples collected in Maine during the 2004-2013 fisheries, the incidence of Black Gill Syndrome was much lower, and detected cases were much less severe, than in 2003.

Effort and Distribution of Effort

Since the 1970s, effort in the fishery (measured by numbers of trips in which shrimp gear is used) has increased and then decreased on several occasions. In the 1980s there was a gradual increase in the total number of trips (Table 5; refer to Table 6 for trips in the state of Maine only) to a peak of 12,497 during the 1987 season. Increases in season length, shrimp abundance, and record exvessel prices, coupled with reduced abundance of groundfish, all contributed to this increase. Effort subsequently fell to 5,990 trips in the 1994 season. Effort nearly doubled between 1994

and 1996 and then declined again from the 1996 level of 11,791 to 1,304 trips in 2002, a year with only a 25-day open season. Effort increased again during 2003–2005 as the seasons were lengthened, to 3,866 trips in 2005. Effort in 2006 dropped to 2,478, likely due to poor market conditions, increased in 2007 to 4,163, and further increased in 2008 to 5,587, the most trips since 1999.

In 2009, the length of the season was increased to 180 days while effort decreased to 3,002 trips, likely caused by limited demand from the processors and poor market conditions. In what turned out to be a 156-day season in 2010, effort increased dramatically to 5,979 trips. The market conditions were improved from prior years in part due to Canada's limited supply and an increase in local markets. In 2011, the truncated 90-day season yielded a higher effort than 2010 with 7,095 trips. The high level of effort was again due in part due to a limited supply in Canada and demand from local markets. In 2012, the number of trips decreased to 3,666 due to the shortened season. The effort further decreased in 2013 to 1,549 trips, likely due to a low quota and poor fishing conditions (Table 5).

Refer to Figure 5 for comparison of 2016 RSA program trawl and trap locations relative to 2013 fishing effort from VTR data.

The number of vessels participating in the fishery in recent years (prior to the 2014 moratorium) has varied from a high of 347 in 1996 to a low of 144 in 2006. In 2013, there were 208 vessels; 182 from Maine, 13 from Massachusetts, and 14 from New Hampshire, including one that landed in both Maine and New Hampshire (according to harvester logbook data). Of the 182 vessels from Maine, 72 were trappers (Table 7).

Prior to 1994, effort (numbers of trips by state and month) was estimated from landings data collected from dealers, and landings per trip information (LPUE) from dockside interviews of vessel captains:

$$Effort = \frac{Landings}{LPUE}$$

Beginning in the spring of 1994, a vessel trip reporting system (VTR) supplemented the collection of effort information from interviews. From 1995 to 2000, landings per trip (LPUE) from these logbooks were expanded to total landings from the dealer weigh-outs to estimate the total trips:

$$Total.Trips = VTR.Trips \frac{Total.Landings}{VTR.Landings}$$

Since 2000, VTR landings have exceeded dealer weigh-out landings, and the above expansion is not necessary. The 1996 assessment report (Schick et al. 1996) provides a comparison of 1995 shrimp catch and effort data from both the NEFSC interview and logbook systems and addresses the differences between the systems at that time. It showed a slightly larger estimate from the logbook system than from the interview system. Thus effort statistics reported through 1994 are not directly comparable to those collected after 1994. However, patterns in effort can be examined if the difference between the systems is taken into account. An additional complication

of the logbook system is that one portion of the shrimp fishery may not be adequately represented by the logbook system during 1994–1999. Smaller vessels fishing exclusively in Maine coastal waters are not required to have federal groundfish permits and were not required to submit shrimp vessel trip reports until 2000. In the 1994–2000 assessments, effort from unpermitted vessels was characterized by catch per unit effort of permitted vessels.

Catch per Unit Effort

Catch per unit effort (CPUE) indices have been developed from NMFS interview data (1983–1994), logbook data (1995–2012), and Maine port interview data (1991–2013) and are utilized as measures of resource abundance and availability (Table 8 and Figure 4). They are typically measured in catch per hour (from Maine interview data) or catch per trip. A trip is a less precise measure of effort, because trips from interviews and logbooks include both trawl and trap trips, and single day trips and multiple day trips (in the spring), and the proportion of such trips can vary from season to season. Also, in some years, buyers imposed trip limits on their boats, and in 2012 and 2013, Maine DMR imposed day-length limits.

Pounds landed per trip (pounds/trip), from VTRs, averaged 1,410 pounds during 1995–2000. In 2001, the catch per trip dropped to 710 pounds, the lowest since 1994, and remained low, at 765 pounds, in 2002. During 2003–2005 pounds per trip averaged 1,407. The increasing trend continued in 2006 with 2,066 pounds per trip. In 2007, the highest pounds per trip of the time series was observed with 2,584 pounds. During 2008–2011, pounds per trip averaged 2,012, with a value of 2,264 in 2010, which is the second highest in the time series. There was a large decrease in 2012 to 1,497 pounds/trip. In 2013, the average pounds landed per trip was 492, with 619 pounds per trawl trip, both the lowest of their time series (Table 8 and Figure 4).

CPUE indices (pounds landed per hour trawling) have also been developed for both inshore (depth less than 55 fathoms) and offshore (depth more than 55 fathoms) areas using information collected by Maine's port sampling program, and agree well with the catch per trip data from logbooks (Table 8 and Figure 4). Maine's inshore trawl CPUE for 2013 was 118 pounds/hour, offshore was 78 pounds/hour, and the season average was 110 pounds/hour, less than half the time series average of 250 pounds/hour (Table 8).

RESOURCE CONDITIONS

Trends in abundance of Gulf of Maine northern shrimp were monitored during 1963–1983 from data collected in the Northeast Fisheries Science Center's (NEFSC) autumn bottom trawl surveys and in summer surveys by the State of Maine (discontinued in 1983). The NEFSC fall survey has continued; however, the survey vessel and gear were modernized in 2009, and this is considered the beginning of a new survey time series for shrimp. A state-federal (ASMFC) survey was initiated by the NSTC in 1984 to specifically assess the shrimp resource in the western Gulf of Maine. This survey is conducted each summer aboard the R/V *Gloria Michelle* employing a stratified random sampling design and shrimp trawl gear designed for Gulf of Maine conditions. An inshore trawl survey has been conducted by Maine and New Hampshire each spring and fall,

beginning in the fall of 2000 (Sherman et al. 2005). The NSTC has placed primary dependence on the ASMFC summer shrimp survey for fishery-independent data used in stock assessment, although the other survey data are also considered. See Figure 6 for a map of the areas covered by the different surveys.

Abundance and biomass indices (stratified geometric mean catch per tow in numbers and weight) for northern shrimp from the ASMFC summer survey from 1984–2016 are given in Table 9 and Figures 7-10 and 21, and length-frequencies by year are provided in Figure 11 and 12. Indices were calculated using data from successful random tows in strata (areas) 1, 3, 5, 6, 7, and 8 only (Figure 7). The series averaged 15.8 kg/tow from 1984 through 1990, then gradually declined to 4.3 kg/tow in 2001. Between 2003 and 2006 the index increased markedly, reaching a new time series high in 2006 (66.0 kg/tow). Although 2006 was a high abundance year, as corroborated by the fall survey index, the 2006 summer survey index should be viewed with caution because it was based on 29 survey tows compared with about 40 tows in most years (Table 9). The summer survey index was 16.8 kg/tow in 2008, and dropped steadily to a time series low of 1.0 kg/tow in 2013. Recent values (for 2012-2016) are well below the time series average of 11.9 kg/tow (Table 9). The 2013, 2014, and 2015 biomass indices were the lowest in the series, with a mean weight per tow of 1.0, 1.7, and 1.3 kg/tow respectively. The 2016 value of 3.8 kg/tow is higher than any of the previous four years but is the fifth lowest in the time series, well below the time series average. The total mean number of shrimp per tow demonstrated the same general trend as biomass over the time series (Table 9 and Figure 9).

The stratified mean catch per tow in numbers of assumed 1.5-year-old shrimp (Table 9, Figure 24, and graphically represented as the first (left-most) size mode in Figures 11 and 12) represents a recruitment index. Although these shrimp are not fully recruited to the survey gear, this index appears sufficient as a preliminary estimate of year class strength. The recruitment index indicated strong (more than 700 per tow) assumed 1987, 1992, 2001, and 2004 year classes. The assumed 1983, 2000, 2002, and 2006 age classes were weak (fewer than 100 per tow), well below the time series mean of 344 individuals per tow. From 2008 to 2010, the recruitment index varied around 500 individuals per tow, indicating moderate but above average assumed 2007, 2008, and 2009 year classes. The index dropped markedly to 44 individuals per tow in 2011. Time series lows (fewer than 10 per tow) were observed in 2012, 2013, and 2015, indicating recruitment failure of the assumed 2011, 2012, and 2014 year classes. In 2014, the index was 116 per tow, reflecting below-average recruitment of the 2013 year class. The recruitment index for the 2016 survey (the assumed 2015 year class) was 226 individuals per tow, the highest since 2010, but still below the time series average of 344 per tow. Surveys since 2011 have shown an unprecedented six consecutive years (2010–2015 year classes) of below-average recruitment.

Mean numbers per tow at size for 2012 – 2016 are too low to be clearly visible in the figure, which uses a constant y-axis scale for the time series (Figure 11). Expanded vertical axes, for the 2012 – 2016 data show that the mean carapace lengths of the assumed age-1.5 shrimp in the 2014 and 2016 surveys were unusually large, suggesting a high growth rate for the 2013 and 2015 year classes (Figure 12).

Individuals larger than 22 mm carapace length (CL) in the summer are expected to be fully recruited to a fishery the following winter (as primarily age 3 and older). Thus survey catches of shrimp in this size category provide indices of harvestable numbers and biomass for the coming winter (Table 9 and Figure 23). The harvestable biomass index exhibited peaks in 1985, 1990, and 1995, reflecting the strong assumed 1982, 1987, and 1992 year classes respectively. The index then trended down through 2001 to a time series low of 1.5 kg/tow, and is indicative of small assumed 1997 and 1998 year classes. The 2001 harvestable index of 1.5 kg/tow represented a time series low, and is indicative of small assumed 1997 and 1998 year classes. From 2003 to 2006, the index increased dramatically, reaching a time series high in 2006 (29.9 kg/tow). The index has declined steadily since 2006 despite above average recruitment of the 2007, 2008, and 2009 year classes discussed above, and reached a new times series low in 2014 (0.2 kg/tow), consistent with the low recruitment of the 2010, 2011 and 2012 year classes. The harvestable biomass index has been increasing since reaching a record low in 2014, but the 2016 value of 1.2 kg/tow is the fifth lowest in the time series, reflecting the failed recruitment of the 2012 and 2014 year classes, and the below average recruitment of the 2013 year class.

An index of spawning stock biomass was estimated by applying a length-weight relationship for non-ovigerous shrimp (Haynes and Wigley 1969) to the abundance of females at each length, and summing over lengths. The spawning biomass index averaged about 4.9 kg/tow during 1984–1993, then declined to an average of 2.7 during 1994–2003, then rose to a time series high of 28.4 in 2006. Since 2006, the index declined to time-series lows (less than 1.0 kg/tow) in 2012–2015, and increased slightly to 1.1 kg/tow in 2016 (Table 9 and Figure 22).

A population egg production index (EPI) was estimated from summer shrimp survey data as the sum of the number of females at length times their fecundity at length:

$$EPI_t = \sum_{L}^{L} N_{tL} Fec_L$$

where t = year, L = carapace length (mm), N = abundance of females, $Fec_L = \text{fecundity at length}$. The length-fecundity relationship was derived from data in Haynes and Wigley (1969) (Richards et al. 2012):

$$Fec_L = -0.198L^2 + 128.81L - 17821$$
 $(r^2 = 0.76)$

The EPI index for Gulf of Maine northern shrimp varied from about 0.3 million to 1.5 million until 2006 when it rose to a high of 5.6 million followed by a steep decline to time series lows in 2012–2015 (<0.2 million; Table 9 and Figure 16). The value was 0.23 million in 2016, the fifth lowest value in the time series.

An index of survival to age 1.5 was estimated for each year class as the log ratio of the number of age 1.5 recruits to the number of eggs that produced each year class, using summer shrimp survey data:

$$S_t = \exp(\ln(R_t) - \ln(EPI_{t-2}))$$

where S = survival index, R = abundance index of recruits (age 1.5), t = year, and EPI is expressed in millions. The survival index was high (greater than 1,000) for the assumed 1999, 2001, and 2004 year classes, and low (less than 20) for the 2006, 2011, 2012, and 2014 year classes (Table 9 and Figure 25). The index for the 2015 year class was 5,291, the highest in the time series. This is encouraging, but it should be noted that estimating the survival index (a ratio) is difficult when abundance is at extreme lows, as is currently the case.

The NEFSC fall survey conducted by the NOAA Ship *Albatross IV* provided an index of northern shrimp biomass from 1968 to 2008 (Table 10 and Figure 8). The index was near time series highs (above 3.0 kg/tow) at the beginning of the time series in the late 1960's and early 1970s. In the late 1970s the index declined precipitously to a time-series low (0.2 kg/tow) in 1977 as the stock collapsed; this was followed by a substantial increase in the mid to late 1980's, reflecting recruitment and growth of the strong presumed 1982 and 1987 year classes. The index continued to vary with the influences of strong and weak year classes through the 1990s and 2000s, and the survey ended in 2008 with values well above the time series mean (>1.8 kg/tow) during its last four years, including the time series high of 6.6 kg/tow in 2006. This high value corresponded with the time series high seen in the ASMFC summer survey the same year (Table 9 and Figure 8). In 2009, the NEFSC fall survey changed vessels, gear and protocols, thus indices since 2009 are not directly comparable to earlier years. The biomass index from the new NEFSC fall survey declined rapidly, from 7.8 kg/tow in 2009 to 0.7 kg/tow in 2015, parallel to trends in the summer shrimp survey and the ME-NH survey (Figure 8, Figure 10, and Figure 14). NEFSC fall survey values for 2016 are not yet available.

The Maine-New Hampshire inshore trawl survey takes place biannually, during spring and fall, in five regions and three depth strata (1 = 5–20 fa (9–37 m), 2 = 21–35 fa (38–64 m), 3 = 36–55 fa (65–101 m)). A deeper stratum (4 = > 55 fa (> 101 m) out to about 12 miles) was added in 2003 (Figure 6). The survey consistently catches shrimp in regions 1–4 (NH to Mt. Desert Is.) and depths 3–4 (> 35 fa (>64 m)), and more are caught in the spring than the fall (Table 11). The stratified geometric mean weights per tow for northern shrimp for the spring and fall surveys using regions 1–4 and depths 3–4 only are presented in Table 11 and Figures 13 and Figure 14. The Maine-New Hampshire spring index rose steadily from 4.2 kg/tow during 2003 to a time series high of 17.9 kg/tow in spring 2011. The index then dropped abruptly, to a time series low of 1.7 kg/tow in 2013 and again in 2015. The preliminary 2016 value was 2.2 kg/tow. Trends in the spring ME/NH survey may be affected by inter-annual variation in the timing of the offshore migration of post-hatch females. However, the low 2013–2016 biomass indices and size and stage structure in the ME-NH survey (Figure 15) are consistent with the 2013–2016 ASMFC summer survey results.

ENVIRONMENTAL CONDITIONS

Ocean temperature has an important influence on northern shrimp in the Gulf of Maine (Dow 1964; Apollonio et al. 1986; Richards et al. 2012; Richards et al. 2016). Survival during the first year of life has been negatively correlated with ocean temperature during two periods: (1) during the time of the hatch and early larval period, and (2) during the late summer when ocean temperatures and water column stratification are reaching their maximum (Richards et al. 2016).

Relatively cool temperatures during these sensitive periods are associated with higher recruitment indices in the summer shrimp survey. Spawner abundance also influences recruitment, with more recruits produced with higher spawner abundance, but environmental influences have increased in importance since around 2000 (Richards et al. 2012).

Spring surface and bottom temperature anomalies (temperature changes measured relative to a standard time period) in offshore shrimp habitat areas in 2016 were relatively high and sea surface temperature (SST) approached the record reached in 2012 (Figures 17A and 17C). Spring temperature anomalies were cooler in 2014 and 2015. Fall temperature anomalies were at record highs in 2012, and have remained relatively high since then; however, the fall bottom temperature anomaly was lower in 2015 (the most recent year of data, Figure 17D).

Sea surface temperature (SST) has been measured daily since 1906 at Boothbay Harbor, Maine, near the center of the inshore nursery areas for northern shrimp. Average winter SST (Feb-Mar) at Boothbay has increased fairly steadily from an average of 0.8° C during 1906-1948 to 3.3° C during 2006-2016 (Figure 17E). Average winter SST during 2016 (4.1° C) was the fourth highest on record since 1906. Late summer SST (July 15-Sept. 1) did not show a similar long term increasing trend during the 20th century, but increased sharply during the mid-1990s, reaching a record high in 2006 (20.2° C). Late summer SST has remained relatively high since the late 1990s (Figure 17F), and was 17.8° C in 2016.

Overall, temperature conditions for northern shrimp have been poor since around 2000. However, temperatures during periods thought to be critical for early life survival were cooler during 2014 and 2015. The 2015 year class appears to have experienced high survival to age 1.5, but not the 2014 year class (Figure 25). Survival indices for the 2016 year class are not yet available. The NSTC notes that accurately estimating survival rates is difficult when the stock is at extremely low levels.

Ocean temperatures also affect timing of the shrimp larval hatch (Richards 2012). The start of the hatch period has become earlier as temperatures have increased, with the hatch in recent years beginning more than a month earlier than it did before 2000 (10% line in Figure 19). The midpoint of the hatch period (50% line in Figure 19) has changed less than the start of the hatch. These trends were not observed during 2014 – 2016, and instead the hatch began later and reached its midpoint later in prior years (roughly 2008 – 2013).

STOCK STATUS

The NSTC utilized an index-based approach to assess stock status of Gulf of Maine northern shrimp. The Traffic Light Approach, developed by Caddy (1999a, 1999b, 2004) and extended by McDonough and Rickabaugh (2014) was applied to the northern shrimp stock to characterize indices of abundance, fishery performance, and environmental trends from 1984 to present. The approach categorizes annual values of each index as one of three colors (red, yellow, or green) to illustrate the state of the population, environmental conditions, and fishery. Red designates

unfavorable conditions or status, yellow designates intermediate values, and green designates favorable conditions or status.

The NSTC applied the Strict Traffic Light Approach (STLA, Caddy 1999a, 1999b and 2004) to a suite of indices (Figure 20). Fishery independent indices included survey total abundance and biomass estimated from the ASMFC summer shrimp and NEFSC fall surveys, and harvestable biomass, spawning stock biomass, recruitment, and early life survival estimated from the ASMFC summer shrimp survey. The survival index represents the number of eggs that survived to become recruits at age 1.5 (loge ratio R/E_{lag 2}, scaled by 1,000,000). Environmental indices included an index of predation pressure on Gulf of Maine northern shrimp that was developed for the benchmark assessment (NEFSC 2014; Richards and Jacobson 2016), and several sources of temperature data for the northern shrimp resource area. Fishery performance indices included commercial CPUE, price per pound, and annual landings value. Price per pound and annual landings values were standardized to 2016 US dollars (www.bls.gov).

Two qualitative stock status reference levels were developed for the traffic light approach, one based on the 'stable period' mean (SPM, 1985–1994), which was the time period used to define the reference points in Amendment 2. The second qualitative status indicator was based on the entire time series of observations. The 20th percentile of the time series (1984-2016) was considered to delineate an extremely adverse state. For fishery dependent and fishery independent indices, red denotes values at or below the 20th percentile, while green denotes values at or above the SPM. For environmental indices, red denotes values at or above the 80th percentile and green denotes values at or below the SPM.

Fishery independent indices of total biomass and spawning biomass have remained at historic lows for the past five years (2012–2016). Recruitment has been low to extremely poor for six consecutive years, and reached a time series low in 2015. The early life survival index for the 2014 year class (observed in the 2015 survey) was low despite cooler spring temperatures observed in inshore nursery areas in 2014. The survival index for the 2015 year class was very high suggesting that an unusually high proportion of the eggs produced in 2015 survived to age 1.5; however recruitment of that year class was weak. The predation pressure index has been lower in recent years (2012–2015), but has generally been high since the late 1990s. Temperatures were at or near record highs in recent years, cooler in 2014 and 2015, and high again in 2016. There were no fishery dependent indices for 2014-2016 due to a fishery moratorium.

The NSTC also examined a subset of key indicators using the Fuzzy Traffic Light Approach (FTLA; McDonough and Rickabaugh 2014). The FTLA gives a finer view of the classification of each indicator in each year. For each indicator, a line graph shows trends in the time series and the relation to the stable period mean (SPM) and 20th percentile levels. A stacked bar graph reflects the proximity of each annual value to the SPM. The greater the proportion of green or red in each stacked bar, the further that year's index is in a favorable or unfavorable direction, respectively, relative to the SPM. A bar that is 100% yellow indicates a value close to the SPM. These reference levels are not management triggers, as they are not defined in the ASMFC Northern Shrimp FMP

or its Amendments. The levels are used to illustrate the current condition of the stock relative to earlier time periods.

The NSTC evaluated 10 indicators using the FTLA, including: 1) total biomass, 2) recruit abundance, 3) spawning biomass, 4) harvestable biomass, 5) commercial fishery CPUE (metric tons landed per trip; fishery closed 2014 – 2016), 6) early life survival, 7) predation pressure index (PPI), 8) spring sea surface temperature at Boothbay Harbor, ME, 9) spring bottom temperature anomaly from NEFSC surveys in shrimp resource areas, and 10) summer bottom temperature from the ASMFC summer shrimp survey (1 – 4 and 6 are also from the ASMFC summer shrimp survey).

Total biomass indices have remained below the 20th percentile during 2012–2016, and are also the lowest biomass estimates on record (Table 9, Table 12, and Figure 21). Similarly, spawning biomass and harvestable biomass indices have remained below the 20th percentile during 2012–2016, and are also the lowest estimates on record (Table 9, Table 12, and Figure 22 and Figure 23).

Recruitment was below the 20th percentile in 2012, 2013, and 2015, with the lowest recruitment on record observed in 2015 and second lowest in 2013 (Table 9, Table 12, and Figure 24). In 2013 and 2015, abundance of recruits was less than one shrimp per tow, as compared to the SPM of 382 shrimp per tow. In 2016, recruit abundance increased to 226 shrimp per tow, but was still well below the SPM. Early life survival (to age 1.5) was at or below the 20th percentile for the 2012 and 2014 year classes, with survival of the 2012 year class the lowest on record and 2011 the second lowest (Table 9, Table 12, and Figure 25). Early life survival of the 2013 and 2015 year classes was above the SPM, however recruitment of those year classes was weak. The survival index for the 2015 year class was the highest on record, possibly reflecting favorable temperatures during the larval period; however it should be noted that accurately estimating survival is difficult when the population is at low levels. The 2012–2013 year classes would be the target of a 2017 fishery.

No commercial catch occurred in 2014, 2015, or 2016 due to a harvest moratorium. In 2013, the last year prior to the moratorium, the catch rate was below the 20th percentile and a record low for the time series (Table 12 and Figure 26).

Trends in the four environmental indicators suggest that conditions have not been favorable for northern shrimp in recent years (Table 13). Predation pressure has generally increased since the late 1990s. During 2009-2011, the PPI was above the 80th percentile; however during 2013-2015 it has fluctuated around a lower level (Figure 27). Sea surface and bottom temperatures were colder in 2015 than in recent years, however an overall rise in temperature since the stable period is evident (Figure 28, Figure 29, and Figure 30), with spring anomalies and summer bottom temperatures in offshore shrimp habitat at or exceeding the 80th percentile from 2011 to 2013 and again in 2016 (Table 13, Figure 29, and Figure 30).

Taken together, the FTLA indicators demonstrate that the Gulf of Maine northern shrimp stock status continues to be critically poor. Total biomass, spawning biomass and harvestable biomass have remained at unprecedented lows for five consecutive years. Recruitment of the 2012 and 2014 year classes were the weakest observed in the 33-year index time series, although recruitment increased marginally in 2016 (2015 year class). The higher survival of the 2013 year class may have reflected reduced fishing effort on the spawning stock. Although the stock remains in critically poor condition, the protection of the 2013 year class and the small increase in recruitment in 2016 could provide a foundation for stock recovery if these year classes survive to spawn successfully.

Accepted definitions of stock collapse include a population at 10% of un-fished biomass (Worm et al. 2009) or at 20% of B_{MSY} (Pinsky et al. 2011). Using summer survey biomass indices and the 1984–1993 "stable period" survey mean as a highly conservative proxy for un-fished biomass, the Gulf of Maine northern shrimp stock was considered collapsed during 2012 – 2015, but was slightly above this threshold in 2016. Using the stable period mean as a proxy for B_{MSY} instead (likely a more reasonable assumption), the stock remains in a collapsed state.

RECOMMENDATIONS

The NSTC bases its recommendations to the Section on its assessment of current stock status, the biology of the species, and the stated management goal of protecting and maintaining the stock at levels that will support a viable fishery on a sustainable resource (Amendment 2 to the FMP, ASMFC 2011).

Short-term commercial prospects for the 2017 fishing season are very poor given the low index of harvestable biomass in 2016. Longer-term prospects have improved slightly with moderate but below-average recruitment observed in 2016.

Indices of total biomass and spawning biomass have remained at unprecedented lows for five consecutive years, including 2016. The 2016 biomass indices were slightly higher than the previous four years, but were the fifth lowest values on record.

Recruitment failure has been observed in three of the past five years (the 2011, 2012, and 2014 year classes). The 2013 year class, which was well below the long-term average recruit abundance, is responsible for the increase in spawning biomass observed in 2016. They are expected to spawn as four-year-old shrimp in 2017, and likely again in 2018. The 2016 recruitment index (the 2015 year class) was also below the long-term average, but was the highest value observed in the past six years.

Long term trends in environmental conditions have not been favorable for northern shrimp in the Gulf of Maine. This suggests a need to conserve spawning stock biomass to help compensate for what may continue to be an unfavorable environment. Given the continued poor condition of the resource, the poor prospects for a 2017 commercial season, and the value of maximizing spawning potential to rebuild the stock, the NSTC recommends that the Section extend the moratorium on fishing through 2017 to build on the conservation gains from the current moratorium.

ACKNOWLEDGMENTS

The Committee sincerely thanks all those people who have contributed to this report through their time and efforts as part of the crew on the *R/V Gloria Michelle* shrimp survey, as selected vessels in the cooperative winter sampling program, and as port samplers, sample processors, and data entry personnel. Their hard work has made this effort possible.

Table 1: U.S. commercial landings (mt) of northern shrimp in the Gulf of Maine, by year (1958–1984, left) or by season (1985–2016, right). Landings by season include the previous December. No shrimp were sold or purchased from cooperative winter sampling in 2014. Landings in 2015 and 2016 are from the RSA Program.

Note that some boats reported both trapping and trawling, and some landed in more than one state.

Table 8: Gulf of Maine northern shrimp trawl catch rates by season. Mean CPUE in pounds/hour towed is from Maine trawler port sampling. Mean catch in pounds/trip is from NMFS weigh-out and logbook data for all catches for all states. Trawl pounds/trip is trawler only catch. Moratorium implemented for 2014 – 2016 seasons.

| Season | Maine | pounds p towing | er hour | Pounds/trip | Trawl lbs/trip |

Green values ≤ SPM; red values ≥ 80th percentile; yellow values > SPM and < 80th percentile. (B) Fuzzy Traffic Light Analysis (FTLA) color proportions indicate proximity of annual indices to the SPM (red = unfavorable; green = favorable).

Appendix 1. NSTC recommendations made and actions taken by the ASMFC northern shrimp Section for management of the Gulf of Maine northern shrimp fishery, 1987–2015 (adapted from 58th SAW Report, NEFSC 2014).

| Fishing Season | Recommendations | Actions Taken |
|-------------------|--|--|
| 1987 | Extension of season to maximum allowedContinuation of mesh regulations | Open season (182 days)Continuation of mesh regulations |
| 1988 | Restriction of season to winter and springContinuation of mesh regulations | Open season (183 days) Continuation of mesh regulations, except 0.25 inch tolerance in codend eliminated |
| 1989 | Extension of season to maximum allowedContinuation of mesh regulations | Open season (182 days) Continuation of mesh regulations Shrimp separator trawls required in April and May |
| 1990 | Extension of season to maximum allowed Continuation of mesh regulations | Open season (182 days) Continuation of mesh regulations Shrimp separator trawls required in December, April, and May |
| 1991 | Extension of season to maximum allowedContinuation of mesh regulations | Open season (182 days) Continuation of mesh regulations Shrimp separator trawls required throughout season |
| 1992 | Restriction of season from January – March Continuation of mesh regulations | Open season (153 days). December 16, 1991 – May 15, 1992. No fishing on Sundays Continuation of mesh regulations Shrimp separator trawls required throughout season Finfish excluder devices required April 1 – May 15 |
| 1993 | Restriction of season from January – March Continuation of mesh regulations | Open season (138 days). December 14, 1992 – April 30, 1993 No fishing on Sundays Continuation of mesh regulations Finfish excluder devices and separator panels required |
| 1994 | Restriction of season from January – March Continuation of mesh regulations | Open season (122 days) December 15, 1993 – April 15, 1994. Continuation of mesh regulations Finfish excluder devices |
| 1995 | Restriction of season from January – March Continuation of mesh regulations | Open season (128 days). December 1, 1994 – April 30, 1995. No fishing Fridays or Sundays (state choice) Continuation of mesh regulations Finfish excluder devices required |
| 1996 | Extension of season to maximum allowed Continuation of mesh regulations | Open season (152 days). December 1, 1995 – May 31, 1996 for mobile gear; no fishing one day per week. Open season (121 days). January 1 – May 31, 1996 for fixed gear (traps) Continuation of mesh regulations |

| Fishing Season | Recommendations | Actions Taken |
|-------------------|--|--|
| 1997 | Restriction of effort in December, April, and May Continuation of mesh regulations | Open season (156 days). December 1, 1996 – May 31. Two 5-day and four 4-day blocks of no fishing. Trap gear may be left untended. Finfish excluder devices required Continuation of mesh regulations |
| 1998 | Restriction of effort in February – March Continuation of mesh regulations | Open season (105 days). December 1, 1997 – May 22, 1998 for mobile gear; no fishing weekends except March 14 – 15 and December 25–31 and March 16 – 31. Open season (65 days). January 1 – March 15 for trap gear. No fishing on Sundays except March 15. Continuation of mesh regulations Finfish excluder devices required |
| 1999 | Restriction of season to 40 days during February – March Continuation of mesh regulations | Open season (90 days). December 15, 1998 – May 25, 1999 for mobile gear. No fishing on weekends plus December 24–25, December 28 – January 1, January 27–29, February 24–26, March 17–31, and April 29–30. Open season (61 days). January 10 – March 10 for trap gear. Continuation of mesh regulations Finfish excluder devices required |
| 2000 | No fishing; closed season | Open season (51 days). January 15 – March 15. No fishing on Sundays. Continuation of mesh regulations Finfish excluder devices required |
| 2001 | Restriction of season to 61 days Continuation of mesh regulations | Open season (83 days). January 9 – April 30. March 18– April 15 no fishing. Experimental offshore fishery in May. Continuation of mesh regulations Finfish excluder devices required |
| 2002 | No fishing; closed season | Open season (25 days). February 15 – March 11. Continuation of mesh regulations Finfish excluder devices required |
| 2003 | No fishing; closed season | Open season (38 days). January 15 – February 27. No fishing on Fridays. Continuation of mesh regulations Finfish excluder devices required |
| 2004 | No fishing; closed season | Open season (40 days). January 19 – March 12. No fishing on weekends. Continuation of mesh regulations Finfish excluder devices required No mechanical shaking of net on vessel |

| Fishing Season | Recommendations | Actions Taken |
|-------------------|--|--|
| 2005 | Landings should not exceed 2,500 metric tons Continuation of mesh regulations | Open season (70 days). December 19 – 30, no fishing on Friday and Saturday; January 3 – March 25, no fishing on weekends. Continuation of mesh regulations Finfish excluder devices required No mechanical shaking of net on vessel |
| 2006 | Landings should not exceed 5,200 metric tons Continuation of mesh regulations | Open season (140 days). December 12 – April 30. 2007 fishing season tentatively set at 140 days. Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2007 | No recommendation against 140- day season Continuation of mesh regulations | Open season (151 days). December 1 – April 30. 2008 fishing season tentatively set at 151 days. Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2008 | No recommendation against 152- day season Maintain fishing mortality at or below the target/threshold | Open season (152 days). December 1 – April 30. 2009 fishing season tentatively set from December to April Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2009 | Landings should not exceed 5,103 metric tons Maintain fishing mortality at or below the target/threshold | Open season (180 days). December 1 – May 29. Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2010 | Landings should not exceed 4,400 to 4,900 metric tons Maintain fishing mortality at or below the target/threshold | Open season (180 days). December 1 – May 29. Closed early on May 5, 2010. Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2011 | • Based on favored fishing mortality rate, landings should not exceed 3,200 metrics tons (F = 0.22) or 4,000 metric tons (F = 0.29) | Open season (136 days). December 1 – April 15. Closed early on February 28, 2011. Continuation of mesh regulations No mechanical shakers allowed on vessel |
| 2012 | Maintain fishing mortality at or below the target value (F = 0.32) Landings should not exceed 1,834 metric tons | Total allowable catch (TAC) of 2,000 metric tons; increased to 2,211 metric tons on January 20, 2012 Trap season start on February 1 with a 1,000 pound landing limit per vessel per day Trawl season start on January 2, 2012 with three landing days a week |
| 2013 | Moratorium on fishing If fishing is allowed, start season after 50% of shrimp have hatched their brood | TAC of 625 metric tons; divided 17% to trap fishery and 83% to trawl fishery Trawl fishery start on January 22, 2013 with two landings days per week Trap fishery start on February 5, 2013 with 6 landings days and an 800 lb limit Landings days modified throughout season |

| Fishing Season | Recommendations | Actions Taken |
|-------------------|---|--|
| 2014 | Moratorium on fishing; the stock has collapsed | Moratorium on fishing Maine DMR contracted one shrimp trawler to collect samples during the winter |
| 2015 | Moratorium on fishing; the stock has collapsed | Moratorium on fishing 25 metric ton RSA for cooperative winter sampling program; 4 trawlers with an 1,800 pounds per trip limit were allowed to sell their landings; 5 trappers had 10 trap and 100 lbs/week limits, no sale. |
| 2016 | Moratorium on fishing; the stock has collapsed | Moratorium on fishing 22 metric ton RSA for cooperative winter sampling program; 4 trawlers with an 1,800 pounds per trip limit and 2 trappers with a 40 traps and 600 pounds per week limit. Selected vessels were permitted to sell their landings |

MEMORANDUM

October 27, 2016

To: Northern Shrimp Management Section

Northern Shrimp Advisory Panel

From: Northern Shrimp Technical Committee

RE: Northern Shrimp Technical Committee's Research Set Aside Recommendation for

the 2017 fishing season and Cooperative Winter Sampling Proposal

The Northern Shrimp Section imposed a moratorium on fishing for the 2014 – 2016 fishing seasons. In the absence of a fishery in 2014, Maine DMR conducted a limited Cooperative Winter Sampling program. The purpose of the program was to collect samples similar to those that might have been collected from commercial shrimp catches if there had been a fishery, in order to continue the Northern Shrimp Technical Committee's (NSTC) time series of biological samples from the Gulf of Maine northern shrimp fishery catches. The 2014 program was expanded and implemented by the ASMFC in 2015 and 2016 through the research set aside (RSA) provision per Addendum 1 to Amendment 2. If the current moratorium is extended through 2017, the NSTC is recommending a maximum RSA of 13.61 metric tons to be used as described below.

Cooperative Winter Sampling Proposal:

For 2017, The NSTC proposes a cooperative winter sampling program similar to that conducted in 2016. Four trawlers would be selected at random among qualified applicants to conduct a minimum of five trips each: one to fish the Massachusetts-New Hampshire area, one to fish the Western Maine area (Kittery to Phippsburg), one to fish the Mid-coast Maine area (Phippsburg to Monhegan), and one to fish the Eastern Maine area (east of Monhegan Island). Participants would be asked to conduct at least three tows per trip, using their standard shrimp-fishing gear, in areas where they would normally fish for shrimp (within their respective region) at that time of year. Two trappers would be selected to fish the Mid-coast Maine area. Fishing would be performed under a special license or Letter of Authorization issued by the respective state agency. The terms and conditions of the special license or LOA would reflect the NSTC's sampling requirements. All fishers would be allowed to sell their landings to offset trip costs (e.g., fuel, bait, ice, and crew). Based on the market price of shrimp landed under the 2016 RSA, no additional compensation is proposed.

Proposed fishing schedule:

Each trawler would be asked to fish about once every two weeks during the period in which northern shrimp migrate into inshore waters to hatch eggs (usually January through early April). Trips would be scheduled, weather allowing, on a mutually agreed upon date, after discussion

between the captain and the state TC member. Trappers would be asked to set traps during the same period, for about 10 weeks, and tend the traps as often as needed.

Sampling Summary:

- Objective: continue the NSTC's time series of biological samples collected from the Gulf of Maine during the winter fishing season
- Four regions: (1) MA/NH, (2) Western ME (Kittery to Phippsburg), (3) Mid-coast, ME (Phippsburg to Monhegan), and (4) Eastern ME (east of Monhegan Island)
- Four trawlers; one trawler per region
 - Five trips per vessel
 - Collect a 2-kg sample from each tow, three tows per trip preferred
 - o 1000 pound trip limit
- Two trappers to fish for approximately 10 weeks in the Midcoast region
 - o Each trapper to collect a 2-kg sample from the catch about once every two weeks
 - 40 trap limit per trapper
 - o Traps hauled as often as necessary
 - o 500 pound weekly limit per trapper

| | MA/NH | ME trawl | ME trap | <u>Total</u> |
|----------------|-------|----------|---------|--------------|
| Total Samples: | 15 | 45 | 10 | 70 |

RSA Total Allowable Catch Proposal: 30,000 pounds or 13.61 metric tons (maximum)

| Trawler limit per trip (lbs) | 1000 | |
|------------------------------|--------|-------------------------|
| Number of trawler-trips | 20 | (5 trips x 4 trawlers) |
| subtotal | 20,000 | (9.07 mt) |
| Trapper limit per week (lbs) | 500 | |
| Number of trapper-weeks | 20 | (10 weeks x 2 trappers) |
| subtotal | 10,000 | (4.54 mt) |
| Total | 30,000 | (13.61 mt) |
