## Northeast Fisheries Science Center Reference Documents

This series is a secondary scientific series designed to assure the long-term documentation and to enable the timely transmission of research results by Center and/or non-Center researchers, where such results bear upon the research mission of the Center (see the outside back cover for the mission statement). These documents receive internal scientific review, and most receive copy editing. The National Marine Fisheries Service does not endorse any proprietary material, process, or product mentioned in these documents.

All documents issued in this series since April 2001, and several documents issued prior to that date, have been copublished in both paper and electronic versions. To access the electronic version of a document in this series, go to http://www.nefsc.noaa.gov/nefsc/publications/. The electronic version is available in PDF format to permit printing of a paper copy directly from the Internet. If you do not have Internet access, or if a desired document is one of the pre-April 2001 documents available only in the paper version, you can obtain a paper copy by contacting the senior Center author of the desired document. Refer to the title page of the document for the senior Center author's name and mailing address. If there is no Center author, or if there is corporate (i.e., non-individualized) authorship, then contact the Center's Woods Hole Laboratory Library ( 166 Water St., Woods Hole, MA 02543-1026).

Editorial Treatment: To distribute this report quickly, it has not undergone the normal technical and copy editing by the Northeast Fisheries Science Center's (NEFSC's) Editorial Office as have most other issues in the NOAA Technical Memorandum NMFS-NE series. Other than the four covers and first two preliminary pages, all writing and editing have been performed by the authors listed within.

Information Quality Act Compliance: In accordance with section 515 of Public Law 106554, the Northeast Regional Office completed both technical and policy reviews for this report. These predissemination reviews are on file at the Northeast Regional Office.

## EXECUTIVE SUMMARY

This assessment of the scup (Stenotomus chrysops) stock along the Atlantic coast (Massachusetts to North Carolina) is an update through 2010 of commercial and recreational fishery catch data, research survey indices of abundance, and the analyses of those data. The scup stock was not overfished and overfishing was not occurring in 2010 relative to the biological reference points established in the 2008 Northeast Data Poor Stocks (DPS) assessment. The fishing mortality rate (F) was estimated to be 0.040 in 2010, below the fishing mortality threshold reference point $=\mathrm{FMSY}=\mathrm{F} 40 \%=0.177$. Spawning Stock Biomass (SSB) was estimated to be 186,262 metric tons $(\mathrm{mt})=411$ million lbs in 2010, above the biomass target reference point $=$ SSBMSY $=$ SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

Reported 2010 landings in the commercial fishery were $4,855 \mathrm{mt}=10.703$ million lbs, about $3 \%$ under the commercial quota. Estimated 2010 landings in the recreational rod-and-reel fishery were $2,605 \mathrm{mt}=5.743$ million lbs, about $85 \%$ over the recreational harvest limit. Total commercial and recreational landings in 2010 were $7,460 \mathrm{mt}=16.446$ million lbs and total commercial and recreational discards were $2,417 \mathrm{mt}=5.329$ million lbs, for a total catch in 2010 of $9,877 \mathrm{mt}=21.775$ million lbs.

Spawning stock biomass (SSB) decreased from about $100,000 \mathrm{mt}$ in 1963 to about $50,000 \mathrm{mt}$ in 1969, then increased to about $75,000 \mathrm{mt}$ during the late 1970 s . SSB declined through the 1980s and early 1990s to less than 5,000 mt in the mid-1990s. With greatly improved recruitment and low fishing mortality rates since 1998, SSB increased to about greater than $100,000 \mathrm{mt}=220$ million lbs since 2004. SSB was estimated to be $186,262 \mathrm{mt}=410 \mathrm{million} \mathrm{lbs}$ in 2010. There is a $50 \%$ probability that SSB in 2010 was between 178,000 and $192,000 \mathrm{mt}$ ( 392 and 423 million lbs). Fishing mortality calculated from the average of the currently fully recruited ages $(2-7+)$ varied between $F=0.1$ and $F=0.3$ during the 1960s and 1970s. Fishing mortality increased during the 1980s and early 1990s, peaking at about $\mathrm{F}=1.0$ in the mid-1990s. Fishing mortality decreased after 1994, falling to less than $\mathrm{F}=0.1$ since 2001, with F in $2010=$ 0.040 . There is a $50 \%$ probability that $F$ in 2010 was between 0.032 and 0.048 . Recruitment at age 0 averaged 92 million fish during 1963-1983, the period in which recruitment estimates are influenced mainly by the assessment model stock-recruitment relationship. Since 1984, recruitment estimates from the model are influenced mainly by the fishery and survey catches at age, and averaged 103 million fish during 1984-2010. The 1999, 2000, and 2008 year classes are estimated to be the largest of the time series, at 204, 222, and 212 million age 0 fish. The 2010 year class is estimated to be well below average at 44 million age 0 fish.

There is no consistent internal retrospective pattern in F, SSB, or recruitment evident in the 2011 updated assessment model. A between-assessment comparison provides another measure of assessment uncertainty due to changes in model estimates. The 2011 assessment estimates of SSB and F are intermediate with respect to the 2008 DPSWG assessment and 2009 update for the same years, and are very similar to those from 2010 update. The 2011 assessment estimates of the size of the 2007 and 2008 year classes are larger compared to previous assessments, while the estimates of the size of the 2006 and 2009 year classes are smaller.

If the landings of scup in 2011 equal the specified Total Allowable Landings (TAL) = $12,020 \mathrm{mt}=26.500$ million lbs, the 2011 median ( $50 \%$ probability) discards are projected to be $1,471 \mathrm{mt}=3.243$ million lbs, and the median total catch is projected to be $13,491 \mathrm{mt}=29.743$ million lbs. The median F in 2011 is projected to be 0.097 , below the fishing mortality threshold $=$ FMSY $=\mathrm{F} 40 \%=0.177$. The median SSB on June 1, 2011 is projected to be $178,008 \mathrm{mt}=392$ million lbs, above the biomass target of SSBMSY $=$ SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

If the total catches of scup in 2012 equal the July 2011 MAFMC recommended Annual Catch Target $(\mathrm{ACT})=24,200 \mathrm{mt}=53.352$ million lbs, the 2012 median landings are projected to be $21,859 \mathrm{mt}=48.191$ million lbs and the 2012 median discards are projected to be $2,341 \mathrm{mt}=$ 5.161 million lbs. The median F in 2012 is projected to be 0.188 , above the fishing mortality threshold $=$ FMSY $=\mathrm{F} 40 \%=0.177$. The median SSB on June 1, 2012 projected to be 168,235 $\mathrm{mt}=371$ million lbs, above the biomass target of SSBMSY $=$ SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

If the stock is fished at the fishing mortality threshold $=\mathrm{FMSY}=\mathrm{F} 40 \%=0.177$ in 2012, median landings are projected to be $20,674 \mathrm{mt}=45.578$ million lbs, with median discards of $2,217 \mathrm{mt}=4.689$ million lbs , and median total catch $=22,897 \mathrm{mt}=50.479$ million lbs. This projected median total catch is equivalent to the Overfishing Limit (OFL) for 2012, and is greater than MSY $=16,161 \mathrm{mt}$ ( 35.629 million lbs) of total catch $(13,134 \mathrm{mt}=28.956$ million lbs of landings plus $3,027 \mathrm{mt}=6.673$ million lbs of discards). The median SSB on June 1, 2012 is projected to be $168,711 \mathrm{mt}=372$ million lbs, above the biomass target of SSBMSY = SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

## BACKGROUND

## Biology

Scup (Stenotomus chrysops) is a schooling continental shelf species of the Northwest Atlantic that is distributed primarily between Cape Cod and Cape Hatteras (Morse 1978). Scup undertake extensive migrations between coastal waters in summer and offshore waters in winter. Scup migrate north and inshore to spawn in spring, with larger scup (age 2 and older) tending to arrive in spring first, followed by smaller scup (Neville and Talbot 1964; Sisson 1974). Larger scup are found during the summer near the mouth of larger bays and in the ocean within 20fathoms ( 120 feet $=37$ meters), and often inhabit rough bottom areas. Smaller scup are more likely to be found in shallow, smooth bottom areas of bays during summer (Morse 1978). Scup migrate south and offshore in autumn as the water temperature decreases, arriving in offshore wintering areas by December (Hamer 1970; Morse 1978).

Spawning occurs from May through August and peaks in June. About 50\% of age-2 scup are sexually mature (about 17 cm total length; Morse 1978), while nearly all scup of age 3 and older are mature. Scup reach a maximum fork length of at least 41 cm and a maximum age of at least 14 years, with a likely maximum of 20 years (Dery and Rearden 1979). The largest and oldest scup sampled in NEFSC surveys $(1973,1978)$ were fish $38-41 \mathrm{~cm}$ (fork length) and 14 years old. The largest and oldest scup in NEFSC commercial fishery samples (1974) was 40 cm (fork length) and 14 years old. The instantaneous natural mortality rate (M) for scup has been assumed to be 0.20 (Crecco et al. 1981, Simpson et al. 1990) in this and all previous stock assessments.

## Fishery Management

The Mid-Atlantic Fishery Management Council (MAFMC) and Atlantic States Marine Fisheries Commission (ASMFC) jointly manage scup under Amendment 8 (1997) to the Scup, Scup, and Black Sea Bass Fishery Management Plan (FMP). The assessment and management unit includes all scup from Cape Hatteras, NC north to the US-Canada border. Tagging studies (e.g., Neville and Talbot 1964; Cogswell 1960, 1961; Hamer 1970, 1979) have indicated the possibility of two stocks of scup, one in Southern New England waters and another extending south from New Jersey waters. However, the lack of definitive locations for tag return data coupled with distributional data from the NEFSC bottom trawl surveys supports the concept of a single unit stock (Mayo 1982).

Amendment 8 to the FMP established a recovery plan for scup under which exploitation rates were to be reduced to $47 \%$ ( $\mathrm{F}=0.72$ ) during 1997-1999, to $33 \%$ ( $\mathrm{F}=0.45$ ) during 2000-2001, and to $21 \%$ ( $\mathrm{F}=0.26$ ) during 2002-2007. These goals were to be attained through implementation of a Total Allowable Catch (TAC) that included a commercial quota and a recreational harvest limit, commercial fishery minimum net mesh, trap vent and fish sizes and closed areas, and recreational fishery minimum fish sizes, possession limits, and closed seasons.

Amendment 12 (1998) to the FMP established a biomass threshold (a proxy for one-half BMSY) for scup based on the three-year moving average of the NEFSC spring bottom trawl survey index of Spawning Stock Biomass (SSB) during 1977-1979, which was perceived to be a period when the stock was near one-half BMSY. The scup stock was considered to be overfished
when the SSB index fell below a value of 2.77 SSB kg per tow. Amendment 12 defined overfishing for scup to occur when the fishing mortality rate exceeded the threshold fishing mortality of Fmax $=0.26$ (as a proxy for FMSY).

Broad scale Gear Restricted Areas (GRAs) for scup were implemented in November 2000 under the framework provisions of the FMP to reduce discards of scup in small mesh fisheries for Loligo squid and silver hake. Two Northern Areas off Long Island were implemented for November through January, while a Southern Area off the mid-Atlantic coast was implemented for January through April. The size and boundaries of the GRAs were modified in late 2000 and again in 2005 in response to commercial fishing industry recommendations.

Amendment 14 (2007) to the FMP defined the biomass target and implemented a stock rebuilding plan for scup. The stock was to fully rebuild to the biomass target by January 1, 2015. The proxy for BMSY was two times the 3-year moving average of the NEFSC spring index of SSB during 1977-1979 noted earlier, or $2 * 2.77=5.54$ SSB kg per tow. A target fishing mortality rate of $\mathrm{F}=0.10$ was to be applied in each year of a 7 year rebuilding period beginning in 2008. A TAC of $4,491 \mathrm{mt}=9.901$ million lbs and corresponding Total Allowable Landings (TAL) of $3,329 \mathrm{mt}=7.339$ million lbs were established for 2008 to achieve the target F .

The current overfished and overfishing definitions are based on revisions to the FMP through Framework 7 (2007) and use the values established in Amendments 12 (1998) and 14 (2007) as follows:

The maximum fishing mortality threshold for each of the species under the FMP is defined as FMSY (or a reasonable proxy thereof) as a function of productive capacity, and based upon the best scientific information consistent with National Standards 1 and 2. Specifically, FMSY is the fishing mortality rate associated with MSY. The maximum fishing mortality threshold (FMSY) or a reasonable proxy may be defined as a function of (but not limited to): total stock biomass, spawning stock biomass, total egg production, and may include males, females, both, or combinations and ratios thereof which provide the best measure of productive capacity for each of the species managed under the FMP. Exceeding the established fishing mortality threshold constitutes overfishing as defined by the Magnuson-Stevens Act.

The minimum stock size threshold for each of the species under the FMP is defined as one-half BMSY (or a reasonable proxy thereof) as a function of productive capacity, and based upon the best scientific information consistent with National Standards 1 and 2. The minimum stock size threshold (one-half BMSY) or a reasonable proxy may be defined as a function of (but not limited to): total stock biomass, spawning stock biomass, total egg production, and may include males, females, both, or combinations and ratios thereof which provide the best measure of productive capacity for each of the species managed under the FMP. The minimum stock size threshold is the level of productive capacity associated with the relevant one-half MSY level. Should the measure of productive capacity for the stock or stock complex fall below this minimum
threshold, the stock or stock complex is considered overfished. The target for rebuilding is specified as BMSY (or reasonable proxy thereof) at the level of productive capacity associated with the relevant MSY level, under the same definition of productive capacity as specified for the minimum stock size threshold.

## Stock Assessment

A peer-reviewed assessment including an analytical population model was accepted in 1995 by SAW 19 (NEFSC 1995). The assessment featured a virtual population analysis (VPA) modeled in the ADAPT framework (Conser and Powers 1990), with commercial and recreational landings and discards at age estimates, and with state and NEFSC abundance indices used for calibration. The 1995 SAW 19 assessment indicated that F in 1993 was 1.3 , and SSB was 4,600 $\mathrm{mt}=10.141$ million lbs. A yield per recruit $(\mathrm{YPR})$ analysis indicated that $\mathrm{Fmax}=0.236$.

The VPA was updated through 1996 and reviewed by the 1997 SAW 25 (NEFSC 1997), but due to concerns over the low intensity of fishery length sampling in the 1990s, uncertainty about the magnitude of commercial discards in the late 1990s, and the ongoing high variability and imprecision of survey indices, the VPA was not accepted as a basis for management decisions. Assessment conclusions were therefore based primarily on trends in NEFSC and state agency survey indices and catch curve analyses using those survey data. The 1997 SAW 25 was able to conclude that in 1996 scup were over-exploited and near record low abundance levels.

The scup assessment was next updated through 1997 and reviewed by the 1998 SAW 27 (NEFSC 1998). Several configurations of a surplus production model (ASPIC; Prager 1994) were reviewed in addition to an updated VPA, but like the VPA, the production model results were not accepted due to concerns over the validity of the input fishery and survey data. An updated YPR analysis was accepted and indicated that Fmax $=0.26$. The 1998 SAW 27 concluded that a VPA or other analytical model formulation for scup would not be feasible until the quality of the input data, particularly the precision of discard estimates, was significantly improved and that scup was over exploited and at a low biomass level.

The 1998 SAW 27 Panel recommended the scup assessment be based on the long-term time series of NEFSC trawl survey indices and fishery catches. The Panel noted that commercial landings were sustained at about $19,000 \mathrm{mt}=41.888$ million lbs annually during the mid-1950s to mid-1960s, and concluded that the stock was likely near BMSY during that period (Figure 1). The nearest subsequent peak in NEFSC survey indices occurred in the late 1970s. Commercial and total fishery catches in the late 1970s were about one-half of those in the 1950s to 1960s, and so the late 1970s were identified as a period when the stock was likely to have been near one-half of BMSY. The Panel considered the NEFSC spring survey series to be most representative of SSB, since older ages were better represented in the age structure than in the NEFSC fall survey or other state agency surveys. The 1998 SAW 27 Panel recommended that the three-year moving average of the NEFSC spring bottom trawl survey index of SSB during 1977-1979 (2.77 SSB kg per tow) be used as the proxy biomass threshold (one-half BMSY) and that Fmax $=0.26$ be used as the proxy fishing mortality threshold (FMSY). Those recommendations were subsequently adopted for the biological reference points in Amendment 12 to the FMP.

The scup assessment was next updated through 1999 and reviewed by the 2000 SAW 31 (NEFSC 2000). The assessment continued to be based on trends in research survey indices and fishery catches and indicated that the stock was overfished and that overfishing was occurring. The stock assessment was reviewed again by the 2002 SAW 35 and included fishery data through 2001 (NEFSC 2002). The assessment was again based on trends in research survey indices and fishery catches, but indicated that the stock was no longer overfished, although the 2002 SAW 35 Panel concluded that stock status with respect to the overfishing definition could not be evaluated due to the uncertainty of F estimates derived from research survey catch curve calculations. The 2002 SAW 35 Panel found sufficient evidence to conclude that the relative exploitation rates had declined in recent years and that survey observations indicated strong recruitment and some rebuilding of age structure.

During 2002-2008, the status of the stock was evaluated by the MAFMC Monitoring Committee using trends in research survey indices and fishery catches. A relative exploitation index based on the annual total fishery landings and the NEFSC spring three-year average SSB index was used as a proxy for F to monitor status with respect to overfishing and provide guidance to the specification of the annual TAC. A projection of the NEFSC spring survey SSB index using assumptions about maturity, partial recruitment to the survey, and the level of future recruitment as indexed by the NEFSC spring survey at age 1 was used in Amendment 14 to the FMP to forecast stock rebuilding and set the F target for 2008-2105. An update to the status monitoring metrics was completed in 2008 to aid in the specification of fishery regulations for 2009. The update indicated that while the stock was overfished in 2007, the exploitation rate was at about the F target, suggesting that overfishing was not occurring in 2007. However, the stock rebuilding progress was slower than forecast by the Amendment 14 projection, with the NEFSC spring 2007 SSB index (three-year average $=1.16 \mathrm{~kg}$ per tow) at only $56 \%$ of the projected 2007 index ( 2.08 kg per tow).

The most recent peer review of the scup assessment was conducted by the 2008 Northeast Data Poor Stocks (DPS) Peer Review Panel (NEFSC 2009), which accepted an ASAP statistical catch at age (SCAA) model (NFT 2008) as the basis for biological reference points and status determination, with fishery and survey catch data through 2007. The new model of scup population dynamics was expected to provide a more stable tool for monitoring stock status and specifying annual fishery regulations than the previous single index-based model. The assessment indicated that the stock was not overfished and overfishing was not occurring in 2008, relative to the revised biological reference points. Fishing mortality was estimated to have decreased rapidly after 1994, with F in $2007=0.054$. With greatly improved recruitment and relatively low fishing mortality rates since 1998, SSB was estimated to have steadily increased to about $119,300 \mathrm{mt}=263$ million lbs in 2007. There was no consistent retrospective pattern in F, SSB, or recruitment evident in the 2008 assessment model. This 2011 assessment update uses the same model configuration as the 2008 DPS (NEFSC 2009) benchmark and 2009-2010 updated assessments (Terceiro 2009, 2010), with fishery and survey catch information through 2010. This 2011 evaluation of stock status is made with respect to the 2008 DPS biological reference points.

## COMMERCIAL LANDINGS

US total commercial landings averaged over $18,000 \mathrm{mt}$ per year from 1950 to 1965, peaking at over $22,000 \mathrm{mt}$ in 1960, and then decreased to less than $10,000 \mathrm{mt}$ per year in the late 1960s. Landings fluctuated between about 5,000 and $10,000 \mathrm{mt}$ from 1970 to the early 1990s and then decreased to about $1,200 \mathrm{mt}$ in 2000, less than $6 \%$ of the peak observed in 1960. Commercial landings have since increased to average about 4,000 mt during 2003-2010 (Figure 1). Reported 2010 landings in the commercial fishery were $4,855 \mathrm{mt}=10.703$ million lbs, about $3 \%$ under the commercial quota. About eighty percent of the commercial landings of scup for the period 1979-2010 were in Rhode Island (38\%), New Jersey (26\%), and New York (16\%; Table 1). The otter trawl is the principal commercial fishing gear, accounting for about $75 \%$ of the total catch during 1979-2010 (Table 2). The remainder of the commercial landings is taken by floating trap (11\%) and hand lines (7\%), with paired trawl, pound nets, and pots and traps each contributing between 1 and $4 \%$.

## COMMERCIAL DISCARDS

The NEFSC Fishery Observer Program has collected information on landings and discards in the commercial fishery since 1989. Northeast Region (NER; ME-VA) discard estimates were raised to account for North Carolina landings. A discard mortality rate of $100 \%$ was assumed because there are no published estimates of scup discard mortality rates. This assumption is based on limited observations and is a point of contention between scientists and fishermen. Previous peer reviews of the assessment have recommended that research be conducted to better characterize the discard mortality rate of scup in different gear types in order to more accurately quantify the absolute magnitude of scup discard mortality (NEFSC 1995, 1997, 1998, 2000, 2002, 2009). Quantifying discards from the commercial fishery is necessary for a reliable scup assessment, but low sample sizes in the past have resulted in uncertain estimates. Despite the uncertainty of the discard data, recent peer review panels have concluded that commercial discarding of scup has been high during most of the last 20 years, generally approaching or exceeding the commercial landings. Since the implementation of the GRAs in 2000, estimated discards as a proportion of the total commercial catch have decreased, averaging 35\%-40\%.

Commercial discards for scup are estimated using geometric mean discards to landings (GMDL) ratios. Ratios of discards to landings by landings level (for trip landings < 300 kg ( 661 lbs), the bycatch fishery; or $=>300 \mathrm{~kg}$, the directed fishery) and half-year are calculated and multiplied by corresponding observed landings from the NEFSC Dealer Report database to provide estimates of discards. Geometric mean rates (re-transformed, uncorrected, mean lntransformed Discards to Landings per trip) are used because the distributions of landings, discards and the ratio of discards to landings on a per-trip basis in the scup fishery are highly variable and positively skewed. Observed trips with both scup landings and discard were used to calculate per trip discard to landings ratios. Only trips with both non-zero landings and discards could be used for this approach to avoid division by zero. The number of trawl gear trips used to calculate geometric mean discard-to-landings ratios (GMDL) by half year for 1997-2008 ranged
from 1 to 104 for trips < 300 kg and from 1 to 35 for trips =>300 kg, with the best sampling occurring since 2003. No trawl gear trips were available for half year two in 1997 and 1999 for trips < 300 kg and for half year two in 1997-2001 for trips => 300 kg . The ratio calculated for half year one was used to estimate discards for half year two when no trawl gear trips were available in half year two. The ratios ranged from 0.03 in 2004 (half year two, trips => 300 kg ) to 121.71 in 1998 (half year one, trips => 300 kg ; Table 3).

The large 1998 directed fishery ratio and subsequent very high annual discard estimate $(111,973 \mathrm{mt})$ was based on one trawl gear trip. About $93 \%$ of the discard from that trip was attributable to a single tow in which an estimated $68.2 \mathrm{mt}(150,000 \mathrm{lbs}$.) of scup were captured. This tow was not lifted from the water and the captain of the vessel estimated the weight of the catch. There has been debate concerning the validity of the catch weight estimate and whether or not it was representative of other vessels or trips in the fishery. However, the observation was reported by a trained NEFSC observer and was therefore included in the initial calculation of the estimate of scup discards (Tables 3-4). Peer reviews of the assessment have since concluded that the 1998 estimate is infeasible, and it has been replaced by the mean of the 1997 and 1999 estimates ( $3,331 \mathrm{mt}$ ) in subsequent tabulations of catch and in subsequent modeling (Tables 5, $9)$.

## RECREATIONAL CATCH

Scup is the object of a major recreational fishery, with the greatest proportion of catches taken in the states of Massachusetts, Rhode Island, Connecticut and New York. Estimates of the recreational catch in numbers were obtained from the NMFS Marine Recreational Fishery Statistics Survey (MRFSS) for 1981-2010. These estimates were available for three categories: type A - fish landed and available for sampling, type B1 - fish landed but not available for sampling and type B2 - fish caught and released. The estimated recreational landings (types A and B1) in weight during 1981-2010 averaged about 2,000 mt per year (Table 5). Estimated 2010 landings in the recreational rod-and-reel fishery were $2,605 \mathrm{mt}=5.743$ million lbs, about $85 \%$ over the recreational harvest limit. Since 1981, the recreational landings have averaged $30 \%$ of the commercial and recreational landings total.

The estimated recreational discard in weight during 1984-2010 ranged from 6 mt in 1999 to a high of 393 mt in 2006, averaging about 100 mt per year (Table 5). The weight of discards has been directly calculated only for those years (1984 and later) for which recreational catch at age has been compiled. In compilations of total fishery catch for earlier years, the recreational discards was assumed to be approximately $2 \%$ of the estimated recreational landings, based on the mean discard percentage for 1984-1996, the time period with catch at age estimates before the implementation of the FMP. No length frequency samples of the scup discard were collected under the MRFSS program before 2005, so recreational discards were assumed to be fish aged 0 and 1 , in the same relative proportions and with the same mean weight as the landed catch less than state regulated minimum fish sizes. An inspection of discard length frequency samples from the New York recreational fishery for 1989-1991 indicated that this assumption was reasonable. Since 2005 length samples of the recreational fishery discard collected in the MRFSS For-Hire Survey sampling have been used the characterize the size frequency of the discard.

The discard mortality rate in the recreational fishery has been reported to range from 0$15 \%$ (Howell and Simpson 1985) and from $0-14 \%$ (Williams, pers. comm.). Howell and Simpson (1985) found mortality rates were positively correlated with size, due mainly to the tendency for larger fish to take the hook deep in the esophagus or gills. Williams more clearly demonstrated increased mortality with depth of hook location, as well as handling time, but found no association with fish size. Based on these studies, a discard mortality rate in the recreational fishery of $15 \%$ has been used in this and previous assessments.

## COMMERCIAL FISHERY LANDINGS AT LENGTH AND AGE

The NER commercial fishery length frequency sampling is summarized in Table 6. Annual sampling intensity has varied from 18 to 687 mt per 100 lengths, with sampling exceeding the informal threshold criterion of 200 mt per 100 lengths since 1994. For this assessment, commercial fishery landings at age beginning in 1984 have been updated through 2010, with samples generally pooled by market category (pins/small, medium, large/mix, jumbo, and unclassified) and by half-year (January-June, July-December); samples were pooled on a quarterly basis (e.g., January-March) for 2004-2010. Estimates of commercial fishery landings at age (Figure 2) and mean weights at age are presented in Tables 7-8.

## COMMERCIAL FISHERY DISCARDS AT LENGTH AND AGE

The intensity of length sampling of discarded scup from the NEFSC Fishery Observer Program declined in 1992-1995 relative to 1989-1991 (Table 9). Sampling intensity ranged from 489 to 335 mt per 100 lengths sampled in 1992-1995, failing to meet the informal criterion of 200 mt per 100 lengths. Sampling intensity improved to 100 mt per 100 lengths in 1996, but then declined to over 200 mt per 100 lengths in 1997-1999. Sampling intensity has generally met the 200 mt per 100 lengths threshold since 2000 . The mean weight of the discard was estimated from length frequency data using a length-weight equation, total numbers discarded were then estimated by dividing total weight by mean weight, and numbers at length were then calculated from the length-frequency distribution. Discards at length were aged using a combination of commercial and survey age-length keys, with discards at age dominated by fish aged 0,1 , or 2 , depending on the year under consideration. Estimates of commercial fishery discards at age (Figure 3) and mean weights at age are presented in Tables 10-11.

## RECREATIONAL FISHERY LANDINGS AT LENGTH AND AGE

For the recreational fishery, length sampling intensity has varied from 45 to 471 mt per 100 lengths. Sampling in all years except one (1984) during 1981-1987 failed to satisfy the above criterion, but since 1987 the criterion has been met except for 1999-2000 (Table 12). Numbers at length for recreational landings were determined from recreational fishery length samples pooled by half-years (January-June; July-December) over all regions and fishing modes, and were converted to numbers at age by applying half-year age-length keys constructed from NEFSC commercial and survey samples. Age-length keys from spring surveys and first and
second quarter commercial samples were applied to numbers at length from the first half of the year, while age-length keys from fall surveys and third and fourth quarter commercial samples were applied to numbers at length from the second half of the year. Estimates of recreational fishery landings at age (Figure 4) and mean weights at age are presented in Tables 13-14.

## RECREATIONAL FISHERY DISCARDS AT LENGTH AND AGE

As noted earlier, no length samples of the discard were routinely collected under the MRFSS program prior to 2005, so recreational discards were assumed to be fish less than state minimum sizes, in the same relative proportions at length as the landed catch less than the respective state minimum sizes (i.e., sub-legal fish). This assumption for the coastwide fishery is supported by discard length frequency samples from the New York recreational fishery (19891991) and samples collected since 2005 by the MRFSS For-Hire Survey. Since 2005, the MRFSS For-Hire Survey discard samples have been used in concert with the MRFSS sub-legal landed lengths to characterize the length frequency of the recreational discard. Numbers at length were converted to numbers at age by applying half-year (January-June; July-December) agelength keys constructed from NEFSC commercial and survey samples. As noted earlier, a 15\% discard mortality rate is assumed. Estimates of recreational fishery discards at age (Figure 5) and mean weights at age are presented in Tables 15-16.

## TOTAL FISHERY CATCH

Estimates of the total fishery catch at age and mean weights at age for 1984-2010 (the time series is limited by the availability of sampled fishery ages) are presented in Tables 17-18. Total commercial and recreational landings in 2010 were $7,460 \mathrm{mt}=16.446$ million lbs and total commercial and recreational discards were $2,417 \mathrm{mt}=5.329$ million lbs, for a total catch in 2010 of $9,877 \mathrm{mt}=21.775$ million lbs (Table 5). An extended time series of the total catch of scup has been estimated to provide an historical perspective of the exploitation of scup in the years before fishery aging data were available (Table 19). These estimates include commercial and recreational landings and discards. The catches before 1981 are the least reliable due to uncertainty about a) the magnitude of domestic commercial fishery discards, b) the magnitude of the distant water fleet (DWF) catch and c) the uncertainty of assumptions made to estimate the recreational catch (50\% reduction from interpolations made in Mayo 1982 for 1960-1978; recreational discards assumed to be $2 \%$ of the adjusted recreational landings). For years in which no commercial fishery observer data were collected (prior to 1989), commercial discards were estimated using the mean of landings to discards ratios for 1989-2001.

## RESEARCH SURVEY INDICES OF ABUNDANCE

## Northeast Fisheries Science Center

The NEFSC spring and fall bottom trawl surveys provide long time series of fisheryindependent indices for scup. The NEFSC spring and fall surveys are conducted annually during

March-May and September-November, ranging from just south of Cape Hatteras, NC to Canadian waters. NEFSC spring and fall abundance and biomass indices for scup exhibit considerable inter-annual variability (Table 20, Figure 6). NEFSC spring survey catches are characterized mainly by scup of ages 1 and 2 (Figure 7), while the fall survey often captures large numbers of age 0 and 1 fish (Figure 8).

The Fisheries Survey Vessel (FSV) Albatross IV (ALB) was replaced in spring 2009 by the FSV Henry B. Bigelow (HBB) as the main platform for NEFSC research surveys, including the spring and fall bottom trawl surveys. The size, towing power, and fishing gear characteristics of the HBB are significantly different from the ALB, resulting in different fishing power and therefore different survey catchability. Calibration experiments to estimate these differences were conducted during 2008 (Brown 2009), and the results of those experiments were peer reviewed by a Panel of three non-NMFS scientists during the summer of 2009 (Anonymous 2009, Miller et al. 2010). The terms of reference for the Panel were to review and evaluate the suite of statistical methods used to derive calibration factors by species before they were applied in a stock assessment context. Following the advice of the August 2009 Peer Review (Anonymous 2009), the methods proposed in Miller et al. (2010), and the precedents set in peerreviews of stock assessments for haddock (Van Eeckhaute and Brooks 2010), yellowtail flounder (Legault et al. 2010), silver and red hake (NEFSC 2011a), and winter flounder (NEFSC 2011b), aggregate and length-based calibration factors were used to convert 2009-2011 spring and fall HBB survey catch number and weight indices to ALB equivalents for use in this stock assessment update (Tables 21-23; Figure 6).

The NEFSC survey indices sometimes appear to mainly reflect the availability of scup to the survey, rather than true abundance, making it difficult to interpret large inter-annual changes in the indices. For example, the 2002 spring biomass index was about twice the second highest spring index, which was observed in 1977 (Figure 6). The spring numeric abundance indices are similar; the 2002 index is the highest observed in the series and about twice the 1970 index. These dramatic increases were evident across all ages in the estimated 2002 spring numbers at age (Table 24; Figure 7). However, the previous fall survey estimates of numbers at age in 2001 had not reflected relatively large values from which the corresponding 2002 spring numbers at age might have been expected to derive (Table 25, Figure 8) nor did they subsequently translate to exceptional indices of biomass in fall 2002 or spring 2003. Spring survey biomass and abundance indices decreased subsequent to 2002, but are still above the low values of the late 1990s. Fall survey abundance and biomass, although highly variable, have about doubled since the late 1990s.

The NEFSC winter survey was started in 1992 primarily as a flatfish survey, was conducted during February, and ranged from Cape Hatteras, NC to the southwestern part of Georges Bank. The winter survey 2002 abundance and biomass indices were, like the spring survey, the largest of the time series (Table 26, Figure 6). Similar to the spring estimates, numbers at age estimated for the 2002 winter survey were also exceptionally large (Table 27, Figure 9). Winter survey abundance and biomass decreased subsequent to 2002, but were still above the low values of the late 1990s. The winter trawl series ended in 2007.

The large differences in the absolute magnitude of NEFSC survey catches of ages 0-2 compared to those of fish at ages 3 and older suggests a substantial difference in survey selection at age between these two aggregate age groups. In the 2008 DPS assessment (NEFSC 2009),
aggregate biomass indices retracted to the lengths of fish ages $0-2$ were constructed for calibration of those ages in the population model (maximum length of 22 cm in the winter, 20 cm in the spring, and 23 cm in the fall series). The 2009-2011 HBB values for these aggregate indices have also been converted to ALB equivalents using length calibration factors (Table 28).

## Massachusetts Division of Marine Fisheries

The Massachusetts Division of Marine Fisheries (MADMF) has conducted spring and fall bottom trawl surveys of Massachusetts territorial waters in May and September since 1978. Survey coverage extends from the New Hampshire to Rhode Island boundaries and seaward to three nautical miles, including Cape Cod Bay and Nantucket Sound. The study area is stratified into geographic zones based on depth and area. The MADMF spring survey catches are characterized mainly by scup of ages 1 and 2, while the fall survey often captures large numbers of age 0 fish. The spring biomass and abundance indices decreased sharply from a high in the early 1980s to relatively low levels through the 1990s, and have since exhibited a variable but increasing trend (Table 29, Figure 10). The MADMF fall abundance index can include large numbers of age 0 fish and therefore can be more variable as it reflects inter-annual variance in recruitment. The fall biomass index exhibits an increasing trend since the mid 1990s (Table 29, Figure 10).

## Rhode Island Division of Fish and Wildlife

The Rhode Island Division of Fish and Wildlife (RIDFW) has conducted spring and fall bottom trawl surveys based on a stratified random sampling design since 1979. Three major fishing grounds are considered in the spatial stratification, including Narragansett Bay, Rhode Island Sound, and Block Island Sound. Stations are either fixed or randomly selected for each stratum. The RIDFW spring survey mainly catches scup of ages 1 and 2 . The spring index shows relatively low scup abundance and biomass through 1999 followed by a steep increase during 2000-2002, in common with the NEFSC and MADMF indices, and high variability since then (Table 30; Figure 11). The RIDFW fall survey is dominated by age 0 scup, and the fall indices show a general increase to a 1993 peak, followed by a steep decline until 1998, and a steady increase since then. The fall series reached a time series peak in 2009 (Figure 11).

The RIDFW implemented a ventless trap survey in cooperation with commercial fishermen beginning in 2005. The cooperative trap survey has a fixed station format, and survey catches are expressed as catch per trap soak hour. The index of age 0 scup from the trap indicates strong recruitment in 2007 and 2010, while the aggregate index of scup abundance has increased steadily since 2005 (Table 31; Figures 11-12). The RIDFW cooperative trap survey data have not yet been included in the calibration of the assessment population model.

## Connecticut Department of Enivornmenta Protection

The Connecticut Department of Environmental Protection (CTDEP) trawl survey program was initiated in May 1984 and encompasses both New York and Connecticut waters of Long Island Sound. The stratified random design survey is conducted in the spring (April-June) and fall (September-October). The CTDEP spring index indicates relatively low abundance through most of the survey period, but have increased substantially since 1999 (Table 32, Figure
13). The CTDEP fall survey, which often catches large numbers of age-0 scup, indicates that recruitment was relatively stable during most of the survey period, but the aggregate fall indices have also increased substantially since 1999. (Table 33, Figures 12-13) Due to vessel engine failure, no complete spring or fall surveys were conducted in 2010. The age compositions of the CTDEP spring and fall surveys generally include a higher proportion of age 2 and older fish than the other state or NEFSC surveys (Figures 14-15).

## New York Department of Environmental Conservation

The New York Department of Environmental Conservation (NYDEC) initiated a small mesh trawl survey in 1985 to collect fisheries-independent data on the age and size composition of scup in local waters. This survey is conducted in the Peconic Bays, the estuarine waters which lie between the north and south forks of eastern Long Island. The NYDEC survey provides age 0,1 , and $2+$ indices of scup abundance. The age 0 indices are generally low over the survey period, with peaks in 2000, 2002, 2003, 2006, and 2007 that may indicate recruitment of strong cohorts in those years (Table 34, Figure 12). In the early years of the survey there often has not been a strong correspondence between the age 0 indices and age 1 and $2+$ indices in the following years (Figure 16).

## New Jersey Bureau of Marine Fisheries

The New Jersey Bureau of Marine Fisheries (NJBMF) conducts a stratified random bottom trawl survey of New Jersey coastal waters from Ambrose Channel south to Cape Henlopen Channel. Latitudinal strata boundaries correspond to those in the NEFSC trawl survey; longitudinal boundaries correspond to the 30, 60, and 90 foot isobaths. Each survey includes two tows per stratum plus one additional tow in each of nine larger strata for a total of 39 tows. The NJBMF survey indices exhibit variable patterns over the early part of the time series. The biomass index reached a minimum in 1996 and then generally increased, peaking in 2007 (Table 34; Figure 17).

## University of Rhode Island Graduate School of Oceanography (URIGSO)

University of Rhode Island Graduate School of Oceanography (URIGSO) has conducted a standardized, two-station trawl survey in Narragansett Bay and Rhode Island Sound since the 1950s, with consistent sampling since 1963. Irregular length-frequency samples for scup indicate that most of the survey catch is of fish from ages 0 to 2 . The aggregate numbers-based index reached a peak in the late 1970s, was relatively low during the late 1990s, and has since generally increased. The 2009 index was the second highest of the time series, after the 1976 value (Table 35, Figure 18).

## Virginia Institute of Marine Science (VIMS)

## Juvenile Fish Trawl Survey

The Virginia Institute of Marine Science (VIMS) has conducted a juvenile fish trawl survey in lower Chesapeake Bay during June-September since 1988. The VIMS age-0 scup
indices show a general decline in recruitment from relatively high levels with peaks in the late 1980s to early 1990s, to relatively low levels from the late 1990s to early 2000s, and the indication of several recent strong year classes (Table 34, Figure 12).

## Chesapeake Bay Multispecies Monitoring and Assessment Program Trawl

 SurveyThe VIMS Chesapeake Bay Multispecies Monitoring and Assessment Program (ChesMMAP) trawl survey is designed to support bay-specific stock assessment activities at both a single and multispecies scale. While no single gear or monitoring program can collect all of the data necessary for quantitative assessments, ChesMMAP was designed to fulfill data gaps by maximizing the biological and ecological data collected for several recreationally and commercially important species in the bay. Total abundance and biomass indices composed mainly of age 0 and 1 fish are available since 2002, and suggest strong recruitment in 2005 and 2010 (Table 36, Figure 19).

## NEAMAP Trawl Survey

The VIMS NEAMAP industry-cooperative survey was started in fall 2006, providing research survey samples in the spring and fall seasons along the Atlantic coast from Rhode Island to North Carolina, in depths of 20-90 feet (9-43 meters). The NEAMAP survey data have not yet been included in the calibration of the assessment population model (Table 37, Figure 19).

## 2011 Updated Fishing Mortality Rate and Stock Size Estimates

Fishing mortality rates and stock sizes were estimated using the ASAP SCAA model (NFT 2008a). The catch at age, mean weight at age, maturity at age, and survey index calibration time series were input as in the 2008 DPS and 2009-2010 updated assessments (NEFSC 2009, Terceiro 2009, 2010). Winter, spring, and mid-year survey indices and all survey recruitment (age-0) indices were compared to population numbers of the same age at the beginning of the same year. Fall survey indices were compared to population numbers one year older at the beginning of the next year. Lognormal error distributions were assumed for the total catch in weight, research survey catch at age calibration indices, internal Beverton-Holt stock-recruitment relationship and parameters, selectivity parameters, annual fishing mortality parameters, survey catchability parameters, and estimated stock numbers at age. A multinomial distribution was assumed for fishery catch at age. Additional model settings including specification of likelihood component emphasis factors (lambdas), size of the deviation factors expressed as standard deviations and penalty functions for extreme fishing mortality estimates were left at the consensus values set in the 2008 DPS assessment.

Summary estimates, estimated January 1 stock size at age in numbers, and estimated fishing mortality (F) at age from the 2011 updated model for 1984-2010 (the years with input fishery catches at age) are provided in Tables 38-40. Spawning stock biomass (SSB) decreased from about $100,000 \mathrm{mt}$ in 1963 to about $50,000 \mathrm{mt}$ in 1969, then increased to about $75,000 \mathrm{mt}$
during the late 1970s. SSB declined through the 1980s and early 1990s to less than 5,000 mt in the mid-1990s. With greatly improved recruitment and low fishing mortality rates since 1998, SSB increased to about greater than $100,000 \mathrm{mt}=220$ million lbs since 2004. SSB was estimated to be $186,262 \mathrm{mt}=410$ million lbs in 2010 (Figures 20-21). There is a $50 \%$ probability that SSB in 2010 was between 178,000 and 192,000 mt ( 392 and 423 million lbs; Figure 22). Fishing mortality calculated from the average of the currently fully recruited ages (2-7+) varied between $F=0.1$ and $F=0.3$ during the 1960s and 1970s. Fishing mortality increased during the 1980s and early 1990s, peaking at about $\mathrm{F}=1.0$ in the mid-1990s. Fishing mortality decreased after 1994, falling to less than $\mathrm{F}=0.1$ since 2001, with F in $2010=0.040$ (Figure 23). There is a $50 \%$ probability that $F$ in 2010 was between 0.032 and 0.048 (Figure 24).

Recruitment at age 0 averaged 92 million fish during 1963-1983, the period in which recruitment estimates are influenced mainly by the assessment model stock-recruitment relationship. Since 1984, recruitment estimates from the model are influenced mainly by the fishery and survey catches at age, and averaged 103 million fish during 1984-2010. The 1999, 2000, and 2008 year classes are estimated to be the largest of the time series, at 204, 222, and 212 million age 0 fish. The 2010 year class is estimated to be well below average at 44 million age 0 fish (Figures 20-21).

There is no consistent internal retrospective pattern in F, SSB, or recruitment evident in the 2011 updated assessment model for terminal years since 2003 (Figures 25-27). A betweenassessment comparison provides another measure of assessment uncertainty due to changes in model estimates. The 2011 assessment estimates of SSB and F are intermediate with respect to the 2008 DPSWG assessment and 2009 update for the same years, and are very similar to those from 2010 update. The 2011 assessment estimates of the size of the 2007 and 2008 year classes are larger compared to previous assessments, while the estimates of the size of the 2006 and 2009 year classes are smaller (Figures 28-30).

## 2008 DPS ASSESSMENT BIOLOGICAL REFERENCE POINTS

The 2008 DPS Peer Review Panel accepted the ASAP SCAA model results as the basis for biological reference points and status determination for scup (NEFSC 2009). Reference points were calculated using the non-parametric yield and SSB per recruit/long-term projection approach adopted for summer flounder (NEFSC 2008a) and the New England groundfish stocks (NEFSC 2008b). In the yield and SSB per recruit calculations, the most recent five year averages were used for mean weights and fishery partial recruitment pattern. For the estimation of MSY and SSBMSY, the cumulative distribution function of the 1984-2007 recruitments (corresponding to the period of input fishery catches at age) was re-sampled to provide future recruitment estimates (mean $=117$ million age 0 fish). The 2008 DPS Peer Review Panel recommended F40\% as the proxy for FMSY, and the corresponding SSBF40\% as the proxy for SSBMSY. The F40\% proxy for FMSY = 0.177, the proxy estimate for SSBMSY = SSB40\% = $92,044 \mathrm{mt}=202.922$ million lbs, and the proxy estimate for MSY = MSY40\% = 16,161 $\mathrm{mt}=$ 35.629 million lbs $(13,134 \mathrm{mt}=28.956$ million lbs of landings and $3,027 \mathrm{mt}=6.673$ million lbs of discards).

## 2011 UPDATED STOCK STATUS

The scup stock was not overfished and overfishing was not occurring in 2010 relative to the biological reference points established in the 2008 Northeast Data Poor Stocks (DPS) assessment. The fishing mortality rate (F) was estimated to be 0.040 in 2010, below the fishing mortality threshold reference point $=$ FMSY $=\mathrm{F} 40 \%=0.177$. Spawning Stock Biomass (SSB) was estimated to be 186,262 metric tons (mt) = 411 million lbs in 2010, above the biomass target reference point $=$ SSBMSY $=$ SSB40\% $=92,044 \mathrm{mt}=203 \mathrm{million} \operatorname{lbs}$ (Figure 31).

## ASSESSMENT UNCERTAINTY CONSIDERATIONS

The 2011 assessment indicates that the stock was well above the biomass target and being fished at well below the fishing mortality threshold in 2010. The high level of 2010 stock abundance is the result of historically low fishing mortality rates and historically high levels of recruitment since the late 1990s. The MSY proxy in terms of total catch is $16,161 \mathrm{mt}$ ( 35.628 million lbs), with total landings of $13,134 \mathrm{mt}$ ( 28.956 million lbs ) and total discards of $3,027 \mathrm{mt}$ ( 6.673 million lbs). The extended catch series estimated for scup (Table 19) indicates that this MSY proxy is a feasible estimate. Total fishery catch is estimated to have averaged about 34,000 mt ( $\sim 75$ million lbs) during 1960-1965, while reported commercial landings alone averaged about $19,000 \mathrm{mt}(\sim 42$ million lbs ) in that period. Therefore, the MSY estimate appears feasible given historical evidence from the fishery. The 2008 DPS Peer Review Panel (NEFSC 2009) advised that a gradual increase in the ABC toward the MSY level would facilitate an evaluation of the performance of the new assessment model and reference points in monitoring stock status, while reducing the risk to the stock due to rapidly increased catch.

## PROJECTIONS

Stochastic projections were made to provide forecasts of stock size and catches in 2010 consistent with the 2008 DPS assessment biological reference points. The projections assume that recent (2005-2010) patterns of discarding will continue over the time span of the projections. Different patterns that could develop in the future due to different trip and bag limits and fishery closures have not been evaluated. One hundred projections were made for each of the 1000 MCMC realizations of 2011 stock sizes from the 2011 updated assessment results using NFT AGEPRO version 4.0.5 (NFT 2011). Future recruitment at age 0 was generated randomly from a cumulative density function of the 2011 updated recruitment series for 1984-2010 (mean recruitment $=103$ million fish). The projected catch estimates in the following text-tables are percentile intervals of the catch distributions for fixed F .

If the landings of scup in 2011 equal the specified Total Allowable Landings (TAL) $=$ $12,020 \mathrm{mt}=26.500$ million lbs, the 2011 median ( $50 \%$ probability) discards are projected to be $1,471 \mathrm{mt}=3.243$ million lbs, and the median total catch is projected to be $13,491 \mathrm{mt}=29.743$ million lbs. The median F in 2011 is projected to be 0.097 , below the fishing mortality threshold $=$ FMSY $=\mathrm{F} 40 \%=0.177$. The median SSB on June 1, 2011 is projected to be $178,008 \mathrm{mt}=392$ million lbs, above the biomass target of SSBMSY $=$ SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

If the total catches of scup in 2012 equal the July 2011 MAFMC recommended Annual Catch Target $(A C T)=24,200 \mathrm{mt}=53.352$ million lbs, the 2012 median landings are projected to be $21,859 \mathrm{mt}=48.191$ million lbs and the 2012 median discards are projected to be $2,341 \mathrm{mt}=$ 5.161 million lbs. The median F in 2012 is projected to be 0.188 , above the fishing mortality threshold $=$ FMSY $=$ F40\% $=0.177$. The median SSB on June 1, 2012 projected to be 168,235 $\mathrm{mt}=371$ million lbs, above the biomass target of SSBMSY $=$ SSB40\% = 92,044 mt $=203$ million lbs.

If the stock is fished at the fishing mortality threshold $=\mathrm{FMSY}=\mathrm{F} 40 \%=0.177$ in 2012, median landings are projected to be $20,674 \mathrm{mt}=45.578$ million lbs, with median discards of $2,217 \mathrm{mt}=4.689$ million lbs, and median total catch $=22,897 \mathrm{mt}=50.479$ million lbs. This projected median total catch is equivalent to the Overfishing Limit (OFL) for 2012, and is greater than MSY $=16,161 \mathrm{mt}$ ( 35.629 million lbs) of total catch $(13,134 \mathrm{mt}=28.956$ million lbs of landings plus $3,027 \mathrm{mt}=6.673$ million lbs of discards). The median SSB on June 1, 2012 is projected to be $168,711 \mathrm{mt}=372$ million lbs, above the biomass target of SSBMSY = SSB40\% $=92,044 \mathrm{mt}=203$ million lbs.

Total Catch, Landings, Discards, Fishing Mortality (F) and Spawning Stock Biomass (SSB) in 2012

Catches and SSB in metric tons

| Total Catch | Landings | Discards | F | SSB |
| :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |
| 24,200 | 21,859 | 2,341 | 0.188 | 168,235 |
| 22,897 | 20,674 | 2,217 | 0.177 | 168,711 |

## ACKNOWLEDGEMENTS

Special thanks to Daphne Cassidy, Grace Thornton and the staff of the NOAA Fisheries NEFSC Population Biology Branch for their timely preparation of the 2010 scup ages used in this assessment update.

Table 3. Summary NEFSC Fishery Observer Program data for scup. Geometric mean discards to landings ratios (GMDL; retransformed, mean In-transformed discards to landings ratios [D/L], per trip) are stratified by half-year period (HY1, HY2) and trip landings level (<300 kg, => 300 kg ). N is number of observed trips with both scup landings and discard, which are used to calculate the ratios. Corresponding dealer landings are from the NEFSC database.

Table 5. Total catch (metric tons) of scup from Maine through North Carolina. Landings include revised Massachusetts landings for 1986-1997. Commercial discards for 1984-1988 calculated as the geometric mean ratio of discards to landings numbers at age for 1989-1993. Commercial discards estimate for 1998 is the mean of 1997 and 1999 estimates.

| Year | Commercial Landings | Commercial Discards | Recreational Landings | Recreational Discards | Total Catch |

Table 19. Extended series of total fishery catch. Catches in metric tons ( mt ). To estimate commercial discards for 1960-1988, D/L ratio for 1989-1997 $=0.504$ was applied to commercial landings. To estimate recreational catch for 1960-1980, 50\% of the Mayo 1982 estimates were included.

|  | N/tow | Kg/tow | N/tow | Kg/tow |
|  | HBB | HBB | ALB | ALB |
| 2009 | 160.99 | 3.85 | 92.52 | 2.68 |
| 2010 | 64.18 | 6.08 | 36.89 | 4.23 |

Table 22. NEFSC trawl survey spring and fall survey indices from the FSV Henry B. Bigelow (HBB) and length calibrated, equivalent indices for the FSV Albatross IV (ALB) time series. Spring and fall strata sets include only offshore strata 1-12, 23, 25 and 61-76 for consistency over entire time series. Indices are the sum of the stratified mean numbers ( $n$ ) at length. The length calibration factors are for the lengths observed in the 2008 calibration experiment and include a constant swept area factor of 0.576 . The effective total catch number calibration factors (HBBIALB ratios) vary by year and season, depending on the characteristics of the HBB length frequency distributions.

| Year | Spring (n) <br> HBB | HBB <br> CV | Spring (n) <br> ALB | Effective <br> Factor |
| :---: | :---: | :---: | :---: | :---: |
| 2009 | 11.98 | 75.1 | 9.58 | 1.25 |
| 2010 | 31.82 | 35.8 | 27.30 | 1.17 |
| 2011 | 26.67 | 76.2 | 11.31 | 2.36 |
| Year | Autumn (n) <br> HBB | HBB <br> CV | Autumn (n) <br> ALB | Effective <br> Factor |
| 2009 | 160.99 | 34.8 | 50.79 | 3.17 |
| 2010 | 64.18 | 35.2 | 31.18 | 2.06 |

Table 23. NEFSC trawl survey spring and fall survey indices at age from the FSV Henry B. Bigelow (HBB) and equivalent indices at age for the FSV Albatross IV (ALB) time series. The spring strata set includes offshore strata 1$12,23,25$, and 61-76. The fall strata set (aged set) includes offshore strata 1, 5, 9, 61, 65, 69, 73, and inshore strata 161, and is different from the fall set used in Tables $\mathbf{2 0 - 2 2}$. Indices at age are compiled after the application of length calibration factors including a constant swept area factor of 0.576 . The effective catch number at age calibration factors (HBBIALB ratios) vary by year and season, depending on the characteristics of the HBB length frequency distributions.

Table 28. NEFSC trawl survey winter, spring and fall survey maximum-length restricted biomass indices from the FSV Albatross IV (ALB) and length calibrated, ALB equivalent indices from the FSV Henry B. Bigelow (HBB) for the spring and fall time series. Spring and fall strata sets include only offshore strata 1-12, 23, 25 and 61-76 for consistency over entire time series. These are the aggregate biomass indices for ages $0-2$ used in the stock assessment ASAP model calibration.

| Year | Winter | Winter CV | Spring | Spring CV | Fall | Fall CV |

# Procedures for Issuing Manuscripts <br> in the <br> Northeast Fisheries Science Center Reference Document (CRD) Series 

## Clearance

All manuscripts submitted for issuance as CRDs must have cleared the NEFSC's manuscript/abstract/ webpage review process. If any author is not a federal employee, he/she will be required to sign an "NEFSC Release-of-Copyright Form." If your manuscript includes material from another work which has been copyrighted, then you will need to work with the NEFSC's Editorial Office to arrange for permission to use that material by securing release signatures on the "NEFSC Use-of-Copyrighted-Work Permission Form."

For more information, NEFSC authors should see the NEFSC's online publication policy manual, "Manuscript/abstract/webpage preparation, review, and dissemination: NEFSC author's guide to policy, process, and procedure," located in the Publications/Manuscript Review section of the NEFSC intranet page.

## Organization

Manuscripts must have an abstract and table of contents, and (if applicable) lists of figures and tables. As much as possible, use traditional scientific manuscript organization for sections: "Introduction," "Study Area" and/or "Experimental Apparatus," "Methods," "Results," "Discussion," "Conclusions," "Acknowledgments," and "Literature/References Cited."

## Style

The CRD series is obligated to conform with the style contained in the current edition of the United States Government Printing Office Style Manual. That style manual is silent on many aspects of scientific manuscripts. The CRD series relies more on the CSE Style Manual. Manuscripts should be prepared to conform with these style manuals.

The CRD series uses the American Fisheries Society's guides to names of fishes, mollusks, and decapod
crustaceans, the Society for Marine Mammalogy's guide to names of marine mammals, the Biosciences Information Service's guide to serial title abbreviations, and the ISO's (International Standardization Organization) guide to statistical terms.

For in-text citation, use the name-date system. A special effort should be made to ensure that all necessary bibliographic information is included in the list of cited works. Personal communications must include date, full name, and full mailing address of the contact.

## Preparation

Once your document has cleared the review process, the Editorial Office will contact you with publication needs - for example, revised text (if necessary) and separate digital figures and tables if they are embedded in the document. Materials may be submitted to the Editorial Office as files on zip disks or CDs, email attachments, or intranet downloads. Text files should be in Microsoft Word, tables may be in Word or Excel, and graphics files may be in a variety of formats (JPG, GIF, Excel, PowerPoint, etc.).

## Production and Distribution

The Editorial Office will perform a copy-edit of the document and may request further revisions. The Editorial Office will develop the inside and outside front covers, the inside and outside back covers, and the title and bibliographic control pages of the document.

Once both the PDF (print) and Web versions of the CRD are ready, the Editorial Office will contact you to review both versions and submit corrections or changes before the document is posted online.

A number of organizations and individuals in the Northeast Region will be notified by e-mail of the availability of the document online.

## Publications and Reports of the

## Northeast Fisheries Science Center

The mission of NOAA's National Marine Fisheries Service (NMFS) is "stewardship of living marine resources for the benefit of the nation through their science-based conservation and management and promotion of the health of their environment." As the research arm of the NMFS's Northeast Region, the Northeast Fisheries Science Center (NEFSC) supports the NMFS mission by "conducting ecosystem-based research and assessments of living marine resources, with a focus on the Northeast Shelf, to promote the recovery and long-term sustainability of these resources and to generate social and economic opportunities and benefits from their use." Results of NEFSC research are largely reported in primary scientific media (e.g., anonymously-peer-reviewed scientific journals). However, to assist itself in providing data, information, and advice to its constituents, the NEFSC occasionally releases its results in its own media. Currently, there are three such media:

NOAA Technical Memorandum NMFS-NE -- This series is issued irregularly. The series typically includes: data reports of long-term field or lab studies of important species or habitats; synthesis reports for important species or habitats; annual reports of overall assessment or monitoring programs; manuals describing program-wide surveying or experimental techniques; literature surveys of important species or habitat topics; proceedings and collected papers of scientific meetings; and indexed and/or annotated bibliographies. All issues receive internal scientific review and most issues receive technical and copy editing.

Northeast Fisheries Science Center Reference Document -- This series is issued irregularly. The series typically includes: data reports on field and lab studies; progress reports on experiments, monitoring, and assessments; background papers for, collected abstracts of, and/or summary reports of scientific meetings; and simple bibliographies. Issues receive internal scientific review and most issues receive copy editing.

Resource Survey Report (formerly Fishermen's Report) -- This information report is a regularly-issued, quick-turnaround report on the distribution and relative abundance of selected living marine resources as derived from each of the NEFSC's periodic research vessel surveys of the Northeast's continental shelf. This report undergoes internal review, but receives no technical or copy editing.

[^0]
[^0]:    TO OBTAIN A COPY of a NOAA Technical Memorandum NMFS-NE or a Northeast Fisheries Science Center Reference Document, either contact the NEFSC Editorial Office ( 166 Water St., Woods Hole, MA 02543-1026; 508-495-2350) or consult the NEFSC webpage on "Reports and Publications" (http://www.nefsc.noaa.gov/nefsc/publications/). To access Resource Survey Report, consult the Ecosystem Surveys Branch webpage (http://www.nefsc.noaa.gov/femad/ecosurvey/mainpage/).

    ANY USE OF TRADE OR BRAND NAMES IN ANY NEFSC PUBLICATION OR REPORT DOES NOT IMPLY ENDORSEMENT.
