Atlantic States Marine Fisheries Commission

Coastal Pelagics Management Board

August 2, 2023
10:15 a.m. – 12:45 p.m.
Hybrid Meeting

Draft Agenda

The times listed are approximate; the order in which these items will be taken is subject to change; other items may be added as necessary.

1.	Welcome/Call to Order *(J. Cimino)*	10:15 a.m.
2.	Board Consent • Approval of Agenda • Approval of Proceedings from November 2022	10:15 a.m.
3.	Public Comment	10:20 a.m.
4.	Consider Approval of Fishery Management Plan Review and State Compliance for Atlantic Cobia for the 2022 Fishing Year *(C. Tuohy)* **Action**	10:30 a.m.
5.	Consider Total Harvest Quota for Atlantic Cobia for the 2024-2026 Fishing Years **Final Action** • Technical Committee Report *(A. Giuliano)* • Consider Setting Total Harvest Quota for 2024-2026	10:50 a.m.
6.	Consider Timeline for Potential Review of State Recreational Allocation for Atlantic Cobia **Possible Action**	11:20 a.m.
7.	Consider 2022 Spanish Mackerel Stock Assessment Update • Presentation of Stock Assessment Report • Presentation of Peer Review Report and Response from South Atlantic Fishery Management Council *(J. Carmichael)*	11:40 a.m.
8.	Update from the South Atlantic Fishery Management Council on Spanish Mackerel Port Meetings *(J. Carmichael)*	12:30 p.m.
9.	Other Business/Adjourn	12:45 p.m.

The meeting will be held at The Westin Crystal City, 1800 Richmond Highway, Arlington, VA; 703.486.1111, and via webinar; click here for details

MEETING OVERVIEW

Coastal Pelagics Management Board
August 2, 2023
10:15 a.m. – 12:45 p.m.
Hybrid

Chair: Joe Cimino (NJ) Assumed Chairmanship: 11/21	Technical Committee Chair: Cobia: Angela Giuliano (MD)	Law Enforcement Committee Rep: Capt. N. Scott Pearce (FL)
Vice Chair: Erika Burgess (FL)	Advisory Panel Chair: Craig Freeman (VA)	Previous Board Meeting: November 8, 2022
Voting Members: RI, NY, NJ, DE, MD, PRFC, VA, NC, SC, GA, FL, SAFMC, NMFS (13 votes)		

2. Board Consent

- Approval of Agenda
- Approval of Proceedings from November 2022

3. Public Comment – At the beginning of the meeting, public comment will be taken on items not on the agenda. Individuals that wish to speak at this time must sign-in at the beginning of the meeting. For agenda items that have already gone out for public hearing and/or have had a public comment period that has closed, the Board Chair may determine that additional public comment will not provide additional information. In this circumstance, the Chair will not allow additional public comment on an issue. For agenda items that the public has not had a chance to provide input, the Board Chair may allow limited opportunity for comment. The Board Chair has the discretion to limit the number of speakers and/or the length of each comment.

4. Fishery Management Plan Review for Atlantic Cobia (10:30-10:50 a.m.) Action

Background

- State Compliance Reports for Atlantic cobia were due on July 1, 2023.
- The Cobia Plan Review Team (PRT) reviewed each state report and compiled the annual FMP Review **(Supplemental Materials)**.
- Rhode Island, New Jersey, Delaware, Maryland, Georgia, and Florida have requested *de minimis* status for their recreational and/or commercial fisheries.

Presentations

- Overview of the FMP Review Report by C. Tuohy

Board actions for consideration at this meeting

- Accept 2023 FMP Review and State Compliance Reports for Atlantic cobia.
- Approve *de minimis* requests for Atlantic cobia.

5. Total Harvest Quota for Atlantic Cobia for 2024-2026 (10:50-11:20 a.m.) Final Action

Background

- The current total harvest quota for Atlantic cobia is 80,112 fish for the 2021-2023 fishing seasons. The same total harvest quota was also in place in 2020.

- This current total quota results in a coastwide recreational quota of 76,908 fish and commercial quota of 73,116 pounds.
- The Cobia Technical Committee met in July 2023 to discuss recommendations for the 2024-2026 total harvest quota **(Supplemental Materials)**.

Presentations

- Technical Committee Report by A. Giuliano

Board actions for consideration at this meeting

- Consider setting the total harvest quota for Atlantic cobia for the 2024-2026 fishing seasons.

6. Timeline for Potential Review of State Recreational Harvest Allocation for Atlantic Cobia (11:20-11:40 a.m.) Possible Action

Background

- Current state-by-state percent allocations of the Atlantic cobia recreational quota are based on states' percentages of coastwide historical landings from 2006-2015.
- The Plan Review Team recommended in last year's FMP Review that the Board discuss whether updates to the recreational harvest allocation are warranted, considering current allocations are based on data through only 2015 and considering the next stock assessment and future specifications.
- The Board Chair requested the Board discuss this at the Summer 2023 meeting.
- Staff identified potential timelines if the Board would like to consider future management action to address state recreational allocations **(Briefing Materials)**.

Presentations

- Overview of current state recreational allocations by C. Tuohy

Board actions for consideration at this meeting

- Consider timeline and potential course of action to address state recreational allocations for Atlantic cobia.

7. 2022 Spanish Mackerel Stock Assessment Update and South Atlantic Fishery Management Council Response (11:40 a.m.-12:30 p.m.)

Background

- The 2022 operational stock assessment for Atlantic Spanish mackerel (SEDAR 78) was completed in May 2022 **(Briefing Materials)**.
- The South Atlantic Fishery Management Council's (SAFMC) Scientific and Statistical Committee (SSC) reviewed and discussed SEDAR 78 from August 2022 through April 2023, and submitted catch level recommendations in April 2023 for South Atlantic Fishery Management Council (SAFMC) consideration **(Briefing Materials)**.
- At their June 2023 meeting, the SAFMC agreed to develop a Framework Amendment to the Coastal Migratory Pelagics FMP to adjust catch levels for Atlantic Spanish mackerel based on the SSC's recommendations and assessment results **(Briefing Materials)**.

Presentations

- Assessment overview
- Peer review summary and SAFMC response by J. Carmichael

8. Update on SAFMC Spanish Mackerel Port Meetings (12:30-12:45 p.m.)
Background • The SAFMC plans to conduct port meetings for king and Spanish mackerel fisheries in 2024 to gain a comprehensive understanding of those fisheries to improve management efforts. • The SAFMC's Mackerel Cobia Committee discussed port meeting planning in June 2023, and noted the need to coordinate with the Commission and state partners to plan the meetings **(Briefing Materials)**.
Presentations • Update on SAFMC port meetings by J. Carmichael

9. Other Business/Adjourn (12:45 p.m.)

DRAFT PROCEEDINGS OF THE

ATLANTIC STATES MARINE FISHERIES COMMISSION

COASTAL PELAGICS MANAGEMENT BOARD

The Ocean Place Resort
Long Branch, New Jersey
Hybrid Meeting

November 8, 2022

These minutes are draft and subject to approval by the Coastal Pelagics Management Board.
The Board will review the minutes during its next meeting.

Draft Proceedings of the Coastal Pelagics Management Board Hybrid Meeting
November 2022

The Coastal Pelagics Management Board of the Atlantic States Marine Fisheries Commission convened in The Monmouth I Room in The Ocean Place Resort, Long Branch, New Jersey, a hybrid meeting, in-person and webinar; Tuesday, November 8, 2022 and was called to order at 10:45 a.m. by Chair Joe Cimino.

CALL TO ORDER

CHAIR JOE CIMINO: I'm going to call us to order. This is the Coastal Pelagics Management Board.

APPROVAL OF AGENDA

CHAIR CIMINO: I'm going to start with Approval of the Agenda. Are there any additions or modifications to the agenda? Okay, seeing none; agenda is approved by consent.

APPROVAL OF PROCEEDINGS

CHAIR CIMINO: We'll look at Approval of the Proceedings from May of 2022. Are there any edits to the proceedings? Seeing none; again, we'll consider that approved by consent.

I don't see many members of the public here, but I will open this up for any public comment on items not on the agenda, and we'll also look at hands for anyone online. Okay, I think we can move through that. We don't see any hands.

UPDATE ON 2022 SPANISH MACKEREL STOCK ASSESSMENT AND PEER REVIEW

CHAIR CIMINO: We're going to move into the 2022 Spanish Mackerel Stock Assessment and Peer Review**.**

Those of you have looked through the material, and have been paying attention to the South Atlantic Council, would probably agree there is no other way to describe this as clear kerfuffle. We're very fortunate to have our good friend, John Carmichael here, who is the Executive Director of the South Atlantic Council.

John is going to do his best to give us a background on the assessment itself. The concerns from the SSC and for the Council, and just the possibilities on what our next steps are. I'm going to turn it over to John, and once again thank him for doing this for us.

PRESENTATION OF 2022 STOCK ASSESSMENT UPDATE TO DATE

MR. JOHN CARMICHAEL: All right, thank you, Joe. It's been a long time since I gave a stock assessment presentation around this table. It's kind of fun, actually, looking forward to it. The stock was recently assessed through SEDAR 78. I'm going to go through a few highlights from that stock assessment. The slides you'll see are from the SSC presentation, our SSC presentation in August.

A couple of them have PDF references, which refer to the SEDAR 78 Assessment Report, all this information is available on the South Atlantic Council website at the SSC meeting, as well as through the SEDAR website under SEDAR 78, you can find all the iterations of the stock assessment report. A little bit of background on the stock and its assessment history. It was previously assessed in SEDAR 28, back in 2012. Here we are in 2022, it's been quite a while since the stock was assessed. Part of that was due to delays from the MRIP telephone survey, the effort survey transition, where this was held off a bit to get the Effort Survey data. Then COVID came along. It was planned to get this thing done several years ago, but as it turned out, it wasn't able to get completed until last year.

Back in SEDAR 28, the stock was not overfished and it was not overfishing. Then in SEDAR 78 recently updated the data to 2020. That is probably the first thing to note, 2020 was the COVID year, and we all know that there were some quirks of data collection during 2020, and certainly some unexpected things happened, as far as recreational effort in particular.

It turns out people really lacked for time. They did this through the operational process, which means it's somewhat streamlined. There is not lots of meetings, there is not a full data workshop. They

get together, talk about some issues, go over the data, do most of the work through webinars.

There was one data scoping call, and through the process four different assessment webinars where the model was discussed. There is a panel that's created and they give input and approval of all the decisions. All of that played out during the year. The main things that were changed going from 28 to SEDAR 78 was the data and the model updates.

Normally when we do an operational, we bring the model framework up to whatever the current state of the art is. Sometimes there are programming changes, et cetera, they take place over the year. If you can imagine adding eight years of data, there were a number of different things added within the model, different ways of approaching uncertainty, and solving and configurations, et cetera.

But the main input changes dealt with the growth model, 28 was a sex-specific growth model, and that's now been abandoned. Just issues with the data, dividing things out by sex, when you're already kind of struggling to get the data together, as well as perhaps less suggestion that the growth is really that different. Natural mortality was updated to the current state of the art for estimating natural mortality and different natural mortality across ages.

There were some revised growth parameters, because the growth model was being updated. Input data updated through 2020, the most significant change there being going from a coastal household telephone survey of MRIP to the FES of MRIP, and it was a shortened time series. The previous model went back into the '50s, this one started in 1986. Prior to 1986 there were some years of significantly higher commercial landings than really what you see now.

There is not a lot of data necessarily to support those to understand, say the age and length comp. That was one of the issues in 28 that the modelers thought perhaps shortening the time series, getting the landings more in line with when you have surveys and length and age comps may make the model perform a little bit better, maybe give it a better chance at estimating stock productivity.

But one of the things that did do was cut out some indication of potentially periods of much higher stock productivity. Then finally, there was some alternative pooling of commercial age comps, due to low sample sizes, this was a big topic of discussion, particularly the samples from the northern area, as we're seeing more and more fish being caught farther to the north. I think it underscores some of the challenges we're going to face as we deal with stocks like this, which cross over what is continuing to be a critical boundary within the NMFS, at least the federal scientific program between the Northeast Center and the Southeast Center, with that break between Virginia, North Carolina, and different data collection programs.

You know different ways of getting the sampling done, and how they approach, you know commercial port sampling and other sampling. There was a thought from some of the fishermen that perhaps there may be more age comps in some of those northern areas than may have been dug up for this assessment.

That was a lot of discussion about the commercial age comps, and their difficulty in actually fitting to what was observed. Then there are the recreational data issues. One of the things first noted was there is a spike in the 2020 data, the terminal year. Not surprising to those who have been following the MRIP transition for many years.

That ended up being primarily in shore mode and in Florida. You have a fishery that's crushing along, I'll show the figure in a little minute of pretty steady landings in 2020 comes and the recreational just starts going through the roof. That was evaluated, there was a working paper. Number 3 developed for it that goes into the detail.

You know burrowing down into the MRIP estimates to see where the high catches are showing up. But

ultimately, you know it sort of comes out, well this is the estimate, and the estimate gets put into the model, and you see how it plays out. While it was evaluated, there wasn't anything like changing the estimate or using an average, or anything like that.

Now we get into some of the actual information. This one is primarily recreational and shrimp bycatch. It just shows you what the discard trends are. There is not a lot of shrimp bycatch, but you can see the recreational data, the general rec in the blue, and then the general rec landings in the gray. The general rec discard is the blue, the landings is the gray, and as you see if you look over to the right, you know it's pretty much a flat trend in the landings and then a big spike at the end in the last few years.

Then in the discards you just see kind of a regular increasing trend, although those also do spike to really series highs there in 2020, and even somewhat in 2019 in this figure, so 2019 might have looked like yeah, kind of like normal, but when 2020 came along, as you can see with those right most points, it really took those landings to somewhere that hadn't been seen before.

Then this is the trend in the commercial landings, so the orange line shows with a current 1986 start year. If you look back in the past you see to the left of that line. That is what was used in SEDAR 28, and you see those high landings. Those slightly to the left, that is in the late '70s, '80s, when the commercial fishery really had some high landings.

Even through information from fishermen that were fishing at that time, they said yeah, they believe that that happened. The fishery exploded, and they really recognized that that was too high of landings, and supported the reduction in harvest that followed. But what you see going from the 1986 model to the current time, is you see high landings, somewhat high landings continuing, and then they dropped down quite a bit. Generally, there is not a lot of trends in those landings from after about 2000, it's fairly flat.

The indices, there are not a lot of indices for this stock. We have a hook and line indices from the Florida trip ticket program. We have an MRIP recreational CPUE with all of the caveats and uncertainties and concerns that go with any MRIP CPUE. Then we have a SEAMAP trawl that gets at the young of the year.

SEAMAP, you know is in the south, so if there is any larva appearing farther north, we're probably not getting them. Importantly is, there was no young of year value in 2020 from SEAMAP due to COVID. The SEAMAP is the gray line, and you can see that that is sort of trending downward on the right most.

Then there was a gap in 2020, we don't know where it went. But also, you notice that both the blue and the orange, which is the hook and line in the MRIP. Both of those dropped from 2019 to 2020. You think about the terminal year, this could be important to what the model is thinking is going on with the stock, because it's going into a period where these indices are saying, oh the stock kind of dropped down in 2020 and some of these indices are you know mid-year.

It's also being told from the landings that there was a lot of catch in 2020, so that's a recipe for the model to think the stock biomass is going down. The SSC reviewed all of this information at their meeting earlier in the year, and some of the issues and challenges that they highlighted were the difficulty in selecting that initial start year.

The change to 1986 didn't come easy. The model didn't seem to really have a strong preference. It didn't give a lot of indication as to what start year was best start year, and it really wasn't very well behaved on that parameter. The limited age composition information, as I mentioned. While natural mortality changed its approach, there still was a lot of difficulty in getting a good, robust estimate of it.

The surveys as I just showed, they're pretty flat. They lacked a lot of contrast, which is really important to knowing how the stock is responding,

and they kind of conflict with landings trends. We had that decline in the surveys in the terminal years and we have landings going way up. There are a lot of pieces of information that aren't really coming together well in this model.

Then of course, which is often the case for our stocks, they were unable to estimate steepness, which is the critical stock recruitment parameter, which gives you an idea of how strong that relationship is. Steepness was fixed and suggesting there is not a very strong stock recruitment relationship for the stock.

That also makes it difficult when you're trying to estimate future, because putting the recruits into the population is critical for your future projections, and when you don't really have steepness, it's hard to know how your stock is going to respond to different levels of SSB in the future. This is what the SSC was faced with. But they did look at the stock status again, you know. They had all those challenges, looking at the results. You see this model is the stock status, as far as there is a stock overfished and stock overfishing. You look at that and say, oh, okay it's pretty good, right? I mean I'm not overfished and I'm not overfishing. That tends to make most people think that oh great, the assessment is doing fine.

This is based on the average of the last three years of that assessment, 2018 through 2020, so it's not capturing, it's not like it's just 2020. It's those last three years, and it's a pretty good spread, and it looks pretty decent. But there is always more to the assessment than this. If we now look into what we're actually seeing, as far as the trends and SSB and fishing mortality here.

The orange lines are the biomass. The one squiggly one with the dots is the actual SSB estimates. The red line with it that is the SSBmsy, so that is the target level. The orange line that it's above over its entire time series, that is the minimum stock size threshold. That's the level you want to stay above, or else your stock is declared overfished.

Then the blue below it, the one with the circles is the actual F estimates, your lighter blue line running through there, that's your Fmsy. You want to be below the Fmsy. The history of this stock is that biomass is trended since 1985 to 2020 kind of up and down, around Bmsy levels and actually in a lot of years quite a bit higher. Never been down to MSST.

F has been at or below Fmsy the whole time series, until noticed right there on the far right 2020, the model wants to drive the F up above Fmsy slightly. Technically, you would say the stock was overfishing in 2020. But because of uncertainty in the terminal year, the status convention in the South Atlantic is using the average of the last three years. The official status comes out, even from this assessment that overfishing is not occurring.

While the stock is dropped down, it's close to the MSY levels, they are still quite a bit above the minimum stock size threshold, so it doesn't appear to be bumping up against, certainly overfished yet, at least in these runs. The important thing here is that, you know you see how this stock has performed pretty well, pretty flat for a lot of years.

The fishermen we heard from, the SSC presentations and Council discussion, agree that that is what they think has really been happening. They said this stock has been amazingly consistent for the last 20, 30 years. Things begin to look a little bit different as I suggested, when you start to look at the projections.

Here we're looking at the landings and the SSB. The SSB is the orange, the blue is the landings, and at the red you have the terminal, the vertical red line that's the terminal year, so that's 2020. Those values to the right of that are what's projected in the stock assessment's projection models. This is where you really start to see the impact of what the assessment is telling you, as far as of interest to management, versus what it may be saying about stock status.

Stock status is the past, it influences management, but it's really not a driving factor for managers. What really matters to us as managers is what can we catch in the future, when we put a management plan in place? The first thing to notice is looking at landings in the blue, over on the right, the darker blue. You see the landings are pretty high in the first couple years of the projections. That's again, because of using the idea of the average landings continuing. If you feed the model the average landings, and we saw the increase in 2019, and big increase in 2020. You're telling the model during what we call the interim period, before you apply a different F. You're telling the model that landings are going to be pretty high.

What the model is doing is it's taking that orange line, which is the stock biomass. Remember, so from 2019 to 2020 we see that orange line dip down. Then because of those higher landings, and with the model not having anything to tell it, there is a lot of fish out there to support those higher landings, you see the biomass level drop considerably.

In 2021 the biomass level is down at the MSST level, and 2022 the biomass level is below MSST, in 2023 the biomass is quite a bit below MSST. It's actually projected to be at the lowest biomass the stock has ever seen during this whole 1986 onward period. That is of quite a bit concern, because the model is taking the stock into a place that none of the history has ever shown it to be at.

This is where I think some of the quirks in that data, the spike that you see in the recreational data, the lack of a juvenile survey, going into a projection period with a trajectory in that stock during your terminal year, really all comes together into what created kind of the management storm. You know if these results carry through, and it's really hard to say just yet.

But if projections like this were to carry through, really, we're going to the fishermen and saying, you have this stock which has been crunching along great for 30 years, but your landings are going to be cut in half. Bear in mind, for a number of years we've been looking forward to this assessment, to potentially give us some increase yield.

Anticipating that fishery effort survey will show higher effort and higher landings over time, show the stock was maybe a little bigger, more productive, and that would help us deal with some of these closures we've been experiencing in the northern zone. I think most of you guys probably know that the commercial fishery in the northern zone has been getting shorter and shorter every year.

This year was the shortest it's been, 2021 the shortest before that, and 2020 the shortest before that. It's kind of hard to rectify from observed data perspective of something like the commercial fishery in the northern zone, that the stock is at an all-time low, because there is just no way the stock can be at an all-time low, and that fishery be having the shortest season it has ever had.

The projections really just don't line up with what we've heard from the fishermen. We heard it loud and clear at the SSC meeting and the Council meeting, and what we're seeing in the actual data that we have to look at this population. This is the real problem with the assessment. In my mind, and I told NMFS, if you all don't want to come talk about it, I will, and I'll give my opinion.

I think that the model does a pretty good job of capturing the history of this stock, when it has full data on the cohorts, and when it's got a fully fished out cohort and it's got a couple years of fishery information, it can do a pretty good job of estimating. But when we project into the future, I just don't have any confidence myself that this model has good projection ability. It's not very predictive. You know that happens sometimes in modeling, you know? It's one thing to observe and describe what happened, but it's another thing to use that to infer the future. To me that is the real core problem we're facing with this model.

The SSC recommendations coming out of this, where they were concerned with those data and fit issues I mentioned. They did not make a BSIA, best scientific information, evaluation or recommendation. They did not provide a revised ABC, and they suggested that a working group be created to provide guidance on some next assessment steps, to see if they can fix the model. If they can get to something that they feel is robust and they have confidence in.

RESPONSE FROM THE SOUTH ATLANTIC COUNCIL

MR. CARMICHAEL: Those recommendations came to the Council at the September 2022 meeting. The assessment was presented, the SSC recommendations were presented, those issues were highlighted. At that meeting the Science Center offered to update the SEDAR 78 results with some revised MRIP estimates, so we had Richard Cody on the phone at the meeting, and talked about some things they could look at to try and revise those MRIP landings that we highlighted, those high observations in 2020, 2021, et cetera.

The plan was that could be done and reviewed by the SSC when it met a few weeks ago at its October meeting. They were able to get that work done, so the SSC met October 25-27. They did review this. This was, there is another presentation on our website here, this is the cover slide that went in detail of those changes.

They had a revised model, and we had updated MRIP values included in it. Here are a few highlights of the MRIP revisions. If you look at the figures on your right, we're seeing the general recreational landings and the general recreational discards. Those are showing the base model and the model with the new MRIP.

Probably the first thing you're looking at is you're saying, there's one line on there. But no there are two lines on there, it's just that the model really didn't respond at all to the revisions in the MRIP data. The changes were primarily 2020, 2021 landings, East Florida, shore mode, state waters and inland. The same components in MRIP have been discussed through the transition many times with many species, and particularly in Florida.

Some of the changes, for example, just as highlighted bullets in 2025. East Florida shore, the state waters went from 2,327 to 223,812 fish. That caught the SSCs eye. They were like, well that's a really big change. How do you change the landings that much and you didn't change the model? The inland went from a million to 400,000, so one went up 200,000 one went down 800,000.

Net change landings went down 600,000, but it didn't really seem to affect the model. You'll also see in 2021, so the previous model didn't have any data for 2021, but now we do have some data for 2021, and we see the Territorial Seas going from 2.5 million to 1.2 million, so they dropped down by 1.3 million fish, and the inland went from 82,000 to 175,000, so up 100,000. The first thing you see there is in 2021 we saw an awful lot of Spanish mackerel available to the recreational fishery, which I think kind of reinforces the idea that there is no way the stock can be as low as the model seems to want to take it in the projections. If a shore based recreational and inshore recreational are able to find that many Spanish mackerel, there must be a lot of Spanish mackerel out there.

The SSC looking at the technical aspects of it, concern with the magnitude of those changes, there are some pretty significant changes, and they really didn't feel like they had a very good explanation for why just looking into the estimates and doing some imputing and some other changes could result in such a huge change in the MRIP estimate.

Rather than, I think giving them more confidence, it probably gave them less confidence. In the model, and certainly in the recreational input data, as far as how well it's representing what's really going on out there in the fishery. Based on the review of the model there, and in particular there is issues with the rec data and the lack of the model response to such changes.

They did not feel the MRIP estimates resolved their concerns. They again did not evaluate the SIA, nor did they recommend a new ABC. The working group just sat there on hold from August through September to October, after the Science Center said they would do some new runs.

But when those new runs didn't really give anybody any more warm and more fuzzy feelings, the working group has now been dusted off, and they're going to develop some terms of reference for additional assessment analyses. The SSC is planning to meet in January via webinar, to review an assessment, I forget which stock.

But they are going to look at the terms of reference, provide them to the Science Center, and let's hope that they will do the runs, and are anticipating additional Spanish model runs coming for the April, 2023 SSC meeting. We're pushing this out a little bit further, and Council we are now extending our timeline, as far as getting started on an actual Amendment.

The SSC is still, the assessment really is still kind of in limbo, in terms of the SSCs model. Where does this leave management? We have ABCs in place. We have existing ABCs, and they're still in effect, and they're in effect until the SSC gives us another ABC, always the case. There is some guidance from NMFS on what to do if say, an assessment is rejected, in terms of ABC. But you know we're not at that point yet.

The assessment hasn't been rejected. As I said, it's still kind of in limbo, and the SSC is still hoping to get something out of it to get something more robust. We're not at the point of say applying the NMFS guidance to say, what do we do now in the interim. But there has been a lot of talk about whether or not these changes can fix SEDAR 78, or whether we need to go back to the drawing board, and maybe do a full benchmark of Spanish, which would be several years, probably five years, best case ten years, most realistic case in the future.

The ABC we have is in place. The ACL is in place. The Amendment actually initiating an Amendment is on hold until we deal with the assessment and get an ABC. But the Council does intend to begin talking about the allocations within Spanish mackerel in December at our upcoming meeting, and applying an allocation decision tool, which Council has developed over a couple years, a way of getting information from a variety of sources and processing it into a way the Council can digest it and use it for allocation decision making. We're going to have some discussions of Spanish, we just won't be at the point of say dealing with new catch levels, etcetera.

What does that mean to us for the stock as we continue to work through this process? You know the stock risk appears low, based certainly on the history and the anecdotal information we've heard from the fishermen, and from our advisors, as far as what they are seeing out there on the water. There is high availability proven in the data.

MRIP landings are high, discards remain high. Commercial sector is reporting large fish, which you go back into that time when the commercial landings were really high, back there in the late '70s. They did not see large fish. That is one of the things that they've noted. You know when they say they were overfishing that stock and they truly believe it, and they did not see the big fish. Now they're saying they see the big fish.

I think also very important is that steadily shortening northern zone seasons. You know through 2022, it just indicates high availability of the stock to those fisheries. The only suggestion of the stock risk arises just in the projections, and they're uniformed by data. They don't have age comp, they don't have CPUE, they don't have surveys to carry into there and tell what's going on with the stock.

It really just becomes kind of an accounting exercise of, how many fish are out there. You apply the F and this is how many can come out. But you don't have any of that other information, that I think this

model really, really needs. I think it needs the age comp; I think it needs the surveys to really get a handle what the population is doing.

Now one risk and one challenge are certainly that management now remains based on the coastal household telephone survey, the old way of doing MRIP, and not the newer FES. Every year we go that we have to convert FES to CHTS, we know that adds to the uncertainty. It certainly adds to a bit of frustration with constituents, because if you go to the MRIP website you're going to get FES estimates.

This creates confusion all the time, because folks will go there, and they'll see a different estimate reported for Spanish mackerel, then what say the Southeast Regional Office is reporting on their quota tracking page or ACL monitoring page, because they are converting back to the CHTS numbers. That's just a hassle that we have to deal with, it creates confusion, and it probably adds uncertainty to the whole process.

The sooner we can get the catch levels updated to the current method of doing MRIP, the better, because it just relieves a lot of that confusion. Then of course, important here is those actions to address the northern zone closures on hold, until we can deal with these issues. Then the last thing is just, what is the question of climate change for this stock? If this stock is shifting north, how long is it going to take for our assessment data system to recognize that is the productivity higher, because the stock is spreading over a larger area? Is it's carrying capacity going up? Is it shifting? We still see fish in the south, so there is not a lot of thought that Spanish is significantly just shifting northward, but it does seem to be some indication of increasing landings northward. There is not a lot in the data yet to really feel like you can hang your hat on it. But certainly, anecdotally in what we're hearing, it does seem to be ramping up a bit, certainly farther north than it has been historically. I think we're getting to the end. Yes, that was the last one. I guess I'll see if there are any questions on that, everyone.

CHAIR CIMINO: Yes, thanks, John. It really is great to have you back presenting stock assessments here with us. I am going to open it up to questions for John on the assessment and all that information presented. Emilie and I have thought about what's next for the Board, and obviously I need opinions on that from all of you.

As you're asking questions, you know keep in mind, we need to figure out our comfort level with exactly what John has said. Do we agree that there is low risk for this stock? Do we have concerns about the timeline? Regarding the northern commercial closures. Emilie, correct me if I'm wrong, but I think we can kind of cover that in the next agenda item a little too.

Not worried so much about that. We can have that discussion later, but questions about the assessment, about where the SSC is, about the timelines. Then just overall communication between the Board and the Council as we go through this. I'll open it up to questions now. Go ahead, Shanna.

MS. SHANNA MADSEN: I just want to echo Joe's sentiments. It's great to have you up here, Dr. Carmichael. You always give an amazing presentation, break it down really well, so thank you so much for being here. I do have a couple questions, so stop me if I'm running on too long. My first question is just a general question. Why did the Subcommittee choose to do an operational assessment, when it had been so long since the last assessment?

MR. CARMICHAEL: Yes, that's partially due to process, partially due to workload management. Our other option is to do what is a research track, which they would go in and look at all the information. It takes about two years. It would have an independent peer review, including the CIE. Because they were using the same model and just updating the data, it felt like the operational approach would give enough of a process to get where they needed to go.

I think people were maybe a little surprised by just how the model has performed, and the difficulty in, you know resolving the natural mortality in the start year and a number of things from that prior SEDAR 28 assessment. The SSC has had a lot of discussion about recommending, you know just stop here and do a benchmark, or research track as we call it. But they realize, you know those are planned several years out, and that could add significant delay, so I think they're feeling a bit of that dilemma.

MS. MADSEN: Follow up. Maybe this is a little bit of guessing, but how are we feeling about the update coming up in April? Do we think that we're going to get there? I don't know if there has been any consideration or discussions just yet of what might change, in order to kind of get us to a different place than where we're ending up right now. Just kind of trying to think into the future.

MR. CARMICHAEL: Yes, and I talked to the analysts about that quite a bit. They do feel like high optimism that they can get it done. That may somewhat depend on exactly what the SSC requests, but they can get a fair amount of things done, they feel like, between January and the April meeting. Whether or not it resolves the issues is a question I think everyone was perhaps surprised that big changes in the MRIP data didn't really give the model much response.

I think that is coming at the terminal year, things are pretty well locked into place by the long history. I think there are more questions as to whether or not minor changes like that or other configuration changes can actually significantly move the needle on this model, because it seems very well locked in where it is. The issues in picking the start year suggest that it is kind of wagging over on that side.

But once you feed it, you know a lot of 20, 30 years of data for a short-lived fish. You know a lot of cohorts have moved through in that time, and those are pretty well locked in to that history. I think you get that stock stability, but what it's going to do on the end we're concerned about here in the projections, is kind of anyone's guess.

I sense some SSC members and others maybe feel like, yeah, not so sure this is going to change a lot. Others with a little higher optimism and kind of feeling like, you know they need to go through this and do everything they can, to try and salvage this model, if possible. If only just in the interest of time, knowing that if they were to just reject it, then it will be several years before another effort can be made.

MS. MADSEN: One more, if you don't mind, last one, I promise. You have up on the screen discussions about how the projections are really uninformed by some of those data. There are no age comps, the CPUE surveys are flat. What would we be looking at? How would a research track or a benchmark be able to potentially better inform those projections?

Do you think it's just a matter of really tearing apart the model and kind of starting over entirely? Are we data limited, like are we unable to incorporate those things into the projections with the data that we currently have? Just kind of thinking out and wondering what is going to change between now and potentially a research track that we're going to be able to better inform those projections.

MR. CARMICHAEL: I think one of the challenges is just this model ending in 2020 with COVID, you know. When COVID started there was a lot of concern that people weren't going to fish, and licenses weren't going to be sold, and what was going to happen, and we saw quite the opposite. People went fishing a lot. You know we see a lot of stocks with increased landings. We see a lot of shore and inshore effort that happened at that time. I think that is just kind of an unfortunate quirk of the timing of this model.

But back in 2020, talking about things, there was a lot of concern about assessment models that would be done with like a 2020 terminal year. What is that data? Things are really different than the past, which is what models' kind of rely on. What is that really going to do, and the loss of surveys was a concern, so we didn't get the juvenile survey. I

don't think that a doing what we have now as a research track would have changed a whole lot, unless maybe it found some more data or some different ways of dealing with like the age data from more northern areas, which some of the fishermen have identified. Basically saying, look I've been sampled, the data are somewhere, that sort of thing. I don't think that would have done much with a 2020 terminal year.

I think if we were to do it and update that to 2021 or 2022, we may get over that COVID hump. We could feed it some more juvenile survey information, the survey for the fishery information. There was some talk about looking at the commercial Florida trip ticket and more detail, and trying to make sure that is as strong as it can be.

I think those things would be likely to create some changes. But it still may struggle to project. To me that's one of the things that is just inherent in a stock assessment model. You just don't know what the fishery characteristics are going to be three years into the future. I just really believe we all need to spend more time, and be more critical of looking at those projections, and thinking do they really capture what is going on?

Because I noticed in assessments, if it happened big time in this one there is a tendency to look at status. If it's not overfished and not overfishing everybody thinks it's great, and that happened here. This model came out, the results are out and people are like, oh yeah, man this looks great. It's not overfished, it's not overfishing.

I'm like, well did you look at what you can catch in 2023? They're like, what? Half what you're catching now. People are like what, wait a minute. I think that that is just something we have to deal with in projections, and you know research track won't help that, unless somebody comes up with a better crystal ball, or some other way that is more robust, you know.

But we all know, like we're talking about the climate change issues. This could be affecting a stock like this, a short-lived fast-growing stock is probably likely to respond quickly to environmental changes, and I think it could be an ongoing challenge for us in the future, with this stock in particular.

CHAIR CIMINO: Thanks, John. Chris.

MR. CHRIS BATSAVAGE: Thank you for the presentation, John. I think you lay out the challenges and risks pretty well. I think you mentioned in 2021 the recreational harvest was also high. Was that also attributed to the shore mode in Florida, or is that from other high recreational landings?

MR. CARMICHAEL: It was shore mode. It was shore mode in multiple states, as I recall in general. But Florida is the one that particularly stood out through this whole time, with their shore mode landings in the transition to FES. But it was high, 2022 I looked at that last week, and you know we don't have the full information in. But through the waves that were done, 2022 looked down a little bit more like historic normal. But with the uncertainty there, all it takes is one really good wave and some high effort, and it could be right back up to where 2020 and 2021 were.

CHAIR CIMINO: Follow up, go ahead, Chris.

MR. BATSAVAGE: Follow up and one other question. Yes, I noticed that the shore-mode harvest the last couple years was much higher than the private boat mode, and in years past it was more on par with private boat. I didn't know if using the old MRIP estimates from the last assessment showed kind of a similar breakdown between the shore mode and the private boat mode, because one result of the revised MRIP estimates is it combined the big bank mode with the pier mode.

In doing that of course, what you catch off the end of a thousand-foot pier is a lot different than what you catch from shore. I didn't know if that might be having an influence on the catch estimates for Spanish mackerel, when you consider just the sheer

number of trips from shore, and the catch rates from piers is factoring into that. There is a question in there somewhere, so didn't know if that kind of played a role, possibly.

MR. CARMICHAEL: Yes, you do. In the old MRIP and in the older years even in CHTS, the boat mode always was the higher proportion of recreational landings than shore. But it's in those last few years, now that data is just being collected through FES, you know and you do see that the shore mode is running away, far exceeding the boat mode, which that's where I think some of the survey changes and stuff may be in question.

I know like the Outer Banks had a pretty darn good year for Spanish this year, you know off the piers and off the beach. Yes, you get that effort cranked up with some pretty good catches, and you are liable to see it spike up again. Yes, it does seem to me, at least, that it is something with CHTS, and it may be as you say, lumping the piers and the shore together could be having an impact.

MR. BATSAVAGE: Thanks, just one final question on the allocation decision that the South Atlantic Council is going to think about in December. How is that going to work, where you have catch estimates or catches from the commercial and recreational fishery now, based on unrevised MRIP, but we're still dealing with the catch in the old currency?

I'm just curious to know what kind of work that the South Atlantic Council can do on allocations now, you know with just that disconnect between catch in the currency and then also the uncertainty in the recreational harvest estimates, especially when you're looking at commercial recreational allocations.

MR. CARMICHAEL: Yes, the intent on that was that we would have the ABC and we would have the recreational now in the CHTS, and we could apply the allocations. If we're going to look at historical years, we'll have that with the CHTS conversion. I mean the FES conversion; I always flip-flop those. No, we have the new MRIP and we would be able to apply that. I think likely what the Council will do to look at the MPS and MRIP updates, and apply that for the allocations. But the intent is that whatever allocation percentage changes might happen, they would be applied in the Amendment that brings in the new ABC. At least at this point there is no plans to try and revise allocations based on new data, and apply them to an ABC based on old data. But we're thinking allocation could be a tough discussion, so it might be worth our time to go ahead and start talking about that anyway.

CHAIR CIMINO: Other questions? Go ahead, Jay.

DR. JASON McNAMEE: Thanks, John, great presentation. Just thinking a little bit about, it just seems like there is not enough information available. Just the discussion we've been having; I don't know what would change the kind of give more information to the statistical model. It's a great group working on it.

I think they would have figured it out, you know if there was something there. I just wondered. I kind of poked around a little bit. You know you made the comment about the research track, how it gets mapped out like, you know pretty far out into the future. But there is a state-space approach research track going on now.

I wondered; did they think about that? Did they think about putting this in as one of the candidates? I think the way they did this was they kind of picked the set of candidate species that they were going to kind of bring into that research track. I wondered if this, I think it's either about to start or maybe just started.

I'm not sure where it's at. It's coming up soon, so was wondering if that was a thought. Maybe there is a way to kind of shoehorn it in sort of late in the game. But that might be a way to sort of get something in a quicker timeframe, using a different tool. My whole point is, I think you need a new tool that might be one it might not, I'm not sure.

MR. CARMICHAEL: Yes, that's a good idea, actually. Top of my head, not sure what the stock are, but Spanish seems to have come out of left field as a surprise, so it might be one that is worth seeing if we can get it in there, especially if there are some distribution shifts going on. That may help.

CHAIR CIMINO: Any other questions? Go ahead, Bob.

EXECUTIVE DIRECTOR ROBERT E. BEAL: Maybe this sort of segues into the next agenda item. But John, as far as timing goes, you know the new work will be done for the April SSC, April SSC does their work, and I assume they are going to report out at the June Council meeting. The June Council meeting, the Council will see the new information.

They've got one of two ways, right? They decide it is good enough, we can base management on this, let's go forward, or they say it's not good enough and then we're stuck, right? Unless, you know Jason's idea works out. You know we're going to have this interim period, where we really don't have much management advice, and the stock is moving.

I think that is going to be our big problem area. If it doesn't work, we may have five years where we really don't have management guidance, and we're trying to manage the stock. The public expects some good news, but we don't have any good news. Is that kind of the dilemma we're potentially in, is this big chunk of time where we don't have any assessment guidance and we need to keep this thing going?

MR. CARMICHAEL: Yes, I think that kind of is how it would play out if the Council gets it in June. I would think if these new runs and iterations of the model don't resolve the issues to the SSCs satisfaction, then I think we would push them to say, well are you at the point of rejecting this model? We can't come back in October with some more runs, like we're going to have to do something a bit more serious and robust to resolve the issues.

I feel, if they can't settle it, if they can't give us a new ABC in April based on this model, then I think we do need to invoke, okay, the model is essentially not informative for ABC. Let's look at our other options in the different data limited approaches, what you do when an assessment is essentially rejected, what you do in the interim, because there is guidance there.

There is stuff in the National Standards. I think we would really have to put that on the table for the SSC, and encourage them to say, okay give us an ABC with the best information you have now. Otherwise, as you say, we're waiting a number of years, and I just don't think that we can hold this existing ABC for another five, six, seven years. That would be a really bad idea.

CHAIR CIMINO: We're kind of coming to time on this issue. As I mentioned, Emilie has given us a lot of thought on where does the Board go next. One thing that she has noted that I want to put out there for all of you too, is that we don't have a technical committee for Spanish mackerel, so just thoughts from the Board on if it's time for that, or are we in a wait, and see?

I'm not sure that we would have any tasks for them at this point, but it is one thing to think about. I am interested in, again, comfort levels and thoughts on what are the Board's next steps, other than are we comfortable with just waiting to see if we get a new ABC next year? Go ahead, Spud.

MR. SPUD WOODWARD: Yes, it's a frustrating situation for us and for the Council, to be in this position of sort of limbo. But I think absent any definitive information on which to move forward, we don't have any choice but a wait and see posture, at least for the short term. I'm interested to learn a little more about, as these fisheries are moving northward.

Where are they actually being prosecuted at, because one of the things that I heard at our South Atlantic Council Mackerel Cobia AP is that with the exception of off of Cape Canaveral, Florida, the

commercial fisheries are being prosecuted in state waters, which prompted one of our commercial fisheries representatives to say, is this a species that should be considered for management under the Commission rather than the Council.

I've tried to artfully deflect that as best I could, but it does raise an interesting question of, and especially in what we're going to be talking about this afternoon, of what are the optimal governance structures for managing changing fisheries. I had to kind of explain, well you know, we depend on SEDAR like the Council depends on SEDAR. It's not like we have our own separate stock status determination that gives us a different answer than the Council would operate on. Is the fishery as it moves northward, is it occurring primarily in state waters, or is it a mixture of state and federal waters? If so, if it's primarily state waters, then we owe ourselves at least the analysis that we did for cobia, you know looking forward into what is the best governance structure in the future. I think that is something we can be doing now, to sort of think about where are the fisheries occurring, where are they likely to occur?

Sort of have that available in our minds, as we move forward with whatever steps we take, assuming that we get something other than what we have. As John politely, I think, communicated. There is a lot of skepticism that we're going to get anything different than what we have, so anyway that's my perspective. Thank you.

CHAIR CIMINO: No, thank you, I really appreciate that. I agree. That kind of goes back into this next agenda item that we have, looking at the regulations and the differences that the states have compared to the federal FMP. But that does kind of sound like the TC task, I think. Spud, that is a consideration. I think Emilie and I can start working on that information. But if that is the kind of thing, we're going to be looking at then we might want to give real consideration to populating a technical committee for help with that. Erika, go ahead, please.

MR. ERIKA BURGESS: John, thank you for your presentation. I appreciate the hours we've been able to discuss the stock assessment and its challenges. The commercial fishery is very important to Florida. It really is a Florida fishery. But the jurisdiction complications for managing Spanish mackerel are challenging, so I would not want to get in front of the Council at this time. Joe, my preference would be to wait and see what comes out of March.

Not only do we have an ASMFC plan and a South Atlantic Fishery Management Council plan, Spanish mackerel is part of a joint FMP at the federal level with the Gulf Council. There are lots of pieces to unravel as we talk about the future of this fishery, and how we manage it moving forward. But in the meantime, I would like to learn more about the growing fishery to the north.

Who are the participants? Where are the landings happening? I think we could use the interim time to really dig in and understand this fishery better, and perhaps bringing in our Advisory Panel to give us sort of a profile of the fishery. In Florida it's complicated again. We have three different types of commercial fishery prosecuting Spanish mackerel. I don't know how complicated it is to the north, but I would like to learn more.

CHAIR CIMINO: I think we're getting a sentiment here, and I certainly agree with all that has been said. Like I said, Emilie and I will look into that and the Commission will look to see, when is the appropriate time for this Board to reconvene, and if we have to do some stuff by e-mail in the interim, I'm sure we can do that.

REVIEW OF DIFFERENCES BETWEEN THE INTERSTATE FISHERY MANAGEMENT PLAN (FMP) AND FEDERAL FMP FOR SPANISH MACKEREL

CHAIR CIMINO: If there aren't any other hands on this item, we'll move into those differences in the State and Federal Management, and I'll turn it over to Emilie.

MS. EMILIE FRANKE: Moving into this presentation, I'll just give a brief overview of the differences between the state and federal FMPs. Again, as we've just discussed, this will probably come up again next year, whenever the Board reconvenes for the next time. We just wanted to remind folks about this, these differences that the Board discussed almost two years ago now in 2020. The last update to the Interstate FMP for Spanish mackerel was the Omnibus Amendment in 2011, and also an Addendum in 2013. Then on the federal side, Spanish mackerel is managed through the federal coastal migratory pelagics FMP. Any management action to consider addressing the differences between the two FMPs was postponed by the Board until completion of the 2022 assessment, which as we just heard is still undergoing revisions.

The differences between the two FMPs exists in terms of the commercial management zones, the commercial trip limits and closures, allowable gears, the recreational season, and also the recreational accountability measures. For the commercial management zones, the Interstate FMP defines the northern zone as New York through Georgia, and also note that Rhode Island did join the management unit in 2021.

Then for the southern zone for the Interstate FMP, the southern zone is just the east coast of Florida. On the other hand, for the Federal FMP, the northern zone is New York through North Carolina, and the southern zone is South Carolina through the east coast of Florida. Moving into the commercial trip limits.

For both the Interstate northern zone and the Federal northern zone, there is a 3,500-pound commercial trip limit. For the Interstate southern zone, which again is just Florida, the trip limit starts at 3,500 pounds, and is reduced throughout the season, depending on the date and how much of the quota has been harvested, and the lowest step there is a 500-pound trip limit.

Under the Interstate FMP, states are not required to close state waters when Federal waters close. Then for the Federal southern zone, which is South Carolina through Florida, the trip limit also starts at 3,500 pounds, and then is reduced by how much of the quota has been harvested. On the Federal side, the Federal Zones close when that Federal Zone's quota has been met.

As John mentioned, just a reminder on some recent federal closures, and as a reminder, the commercial season is March through February for both the Federal and Interstate FMPs. In the most recent four seasons, including this season, the Federal northern zone has closed by the summertime, so June, July or August.

In recent years when this happened, Maryland, Virginia and North Carolina have all implemented a reduced trip limit in state waters as well. They implemented a 500-pound trip limit. Then in the Federal southern zone, that zone has closed in two out of the most recent four years, and that closure typically occurs closer to the end of the season in January or February.

Moving on to the gear differences. The main difference here is that the Interstate FMP lists the prohibited gears for each sector, while the Federal FMP lists which gears are allowable. Then for the recreational season, the difference here is that the Interstate FMP specifies a calendar year season, while the Federal FMP specifies a March through February recreational season.

Then finally here for recreational accountability differences on the next slide. Under the Interstate FMP, if the total ACL is exceeded and the stock is overfished, then the recreational quotas are decreased via reduced bag limits the following year. Under the Federal FMP, if the total ACL is exceeded, the bag limits are also reduced, but if the stock is also overfished then there is a payback reducing the annual catch target. There are just some slight updates, I think. You know if the Board takes action in the future to align, you know what the Omnibus Amendment describes as the quota, just to align the

terminology to have it consistent with the Federal FMP. That wraps up my presentation on the differences. Again, I think this is something that will come up again next year if the Board needs to consider any sort of Spanish mackerel action, you know following what the Council does in the coming months. Happy to take any questions.

CHAIR CIMINO: Questions. Go ahead, Lynn.

MS. LYNN FEGLEY: Yes, and I'm not sure this question is going to make sense. But we were just talking about, we are potentially staring down the barrel of a reallocation, and I'm wondering how this misalignment would impact that conversation, or if it does.

MS. FRANKE: That is a good question. I might turn to John for some help, but I mean in terms of the allocation between the commercial and recreational sectors. I'm not sure the misalignment would have too much of an impact, more than what we already have, in terms of the different northern and southern zones. I'll see John, is there anything you want to add to that?

MR. CARMICHAEL: No, I think that's right. The first discussion the Council will have will be the Commercial/Rec allocation. That is the primary bit. Then I don't know if there has been a lot of thought about any shifting within those commercial zones at this time. It should be pretty informative, what gets put on the table in December, I suppose, see what Council members bring up.

MS. FRANKE: Just to remind folks, the current allocation is 55 Commercial, 45 Recreational.

CHAIR CIMINO: Yes, and I think part of this goes back to what Spud was saying. Where are these fisheries prosecuted? Because if we don't have a requirement in our plan to go to that reduced trip limit, then one of the questions becomes, do states have the authority to do that on their own? Fortunately, the main states in that northern zone from North Carolina are able to and have been doing that. That becomes a question for us as well. Other questions for Emilie, or thoughts on this? Go ahead, Lynn.

MS. FEGLEY: Is there any particular timeline or urgency to address this misalignment? I ask that, because I think that this really does feed back to the conversation about really digging into the distribution of our landings. Where are these landings happening? Are they in state waters or are they in Fed waters?

It seems like one path forward would be to, rather than trying to align ourselves with the Federal Plan, to separate ourselves from the Federal Plan. I'm just kind of wondering if one thing has to happen before the other, or do they happen together, or if we even want to think about taking back Spanish mackerel.

CHAIR CIMINO: Go ahead, Spud.

MR. WOODWARD: Well, when this came up at the Advisory Panel meeting, you know Council staff were quick to say well, you know, one of the first things we do is we take those ten criteria that you use to say whether a species should be subject to Federal management, and you sort of run them back through that with what is the current situation with the fishery.

I think part of what we'll be doing is sort of taking, okay what do we know about the way Spanish mackerel fishery works now along the coast. Run it back through those criteria. Look at how those criteria apply to it, and use that as sort of the first filter of whether, should we even consider moving from a joint management environment to an Interstate/Commission management environment.

I will certainly look to you all in North Carolina northward. The other thing I heard pretty clear and loud from the guys that are fishing entanglement gear north of Lookout is, please keep giving us our 500-pound closed season allowance, because they're fishing on species where it goes back to what John was saying.

You've got an abundant and widely distributed stock, and they can't avoid them. If you take away that 500-pound, you might as well call it a bycatch allowance, then you're going to have a lot of bycatch and you're going to have a lot of waste. They're saying, until we can reconfigure this fishery to something different than what it is. Please don't take that away, because that's preventing a lot of waste that would be unavoidable otherwise.

MS. FRANKE: I think also, partly in response to Lynn's question, in terms of addressing this alignment maybe sooner rather than later. One of the things that Council could potentially address at some point is this issue of the northern zone closure. If the Council does take action on that, it might be beneficial to wait and see what their action might be. If the Board does want to align, or not align with the Council FMP. We at least know what the Council's next step might be. I think there are still a lot of question marks as to potential action the Council might take next year.

CHAIR CIMINO: Spud and then Chris.

MR. WOODWARD: Yes, just a follow up on that and too, just maybe to allay some fears. I think our plans, and Mel and John can correct me if I'm wrong, with using this allocation decision free tool, is just sort of try it out. Want to see, okay here is where we are with our ABCs our ACLs. You know we're going to run again, what's the fishery. We're going to run it through this tool, and just say okay, what would we do different if we wanted to. That doesn't mean that we're committing ourselves to any course of action by using that decision tree.

Is that what we all agree? We've developed this tool. You know it takes, basically the biology, the ecology, the social, the economic and it's designed to merge all that together if you give us something other than just the traditional, historic catch history, you know kind of approach to it. But I don't think anybody is saying, well we're going to take whatever that tool for this as an output, and immediately put it into an amendment or something. I mean that is certainly not my understanding.

MR. CARMICHAEL: Yes, the important thing about the tool, and this was stressed by staff when we were developing it, and Council was approving the concept, is it doesn't give you the answer. It gives you a process for getting to an answer and evaluating alternatives. But it's not the kind of thing where you're going to plug in data, spit out the results and say okay, there you go.

You know it's really kind of a way to make sure you go through all the different pieces of data for each stock each time, and you're consistent in looking at it across stocks, and how you evaluate things. But like Spud said, it doesn't give you the answer, and it certainly doesn't obligate you then to go in and change the allocation as well. Yes, it's hard to say where that will play out, and as we've not used it a whole lot, so it's a very new thing. This will be one of the first real applications of it, and see where it takes us.

CHAIR CIMINO: Go ahead, Chris.

MR. BATSAVAGE: As stated before, we're really not in a position to address the misalignment between the two plans. We're handling it on an ad hoc basis, more or less, when it comes to dealing with commercial trip limits after the Federal ACL closes, for instance. But looking at the list of things that are kind of misaligned, a couple points to think about for this Board and the Council, when the Council moves forward on an amendment.

The 3,500-pound trip limit to start things off, is it constrained to any of the fishery or barely any of the fishery? None of that has been discussed by the Council before, and you'll see some pushback from the commercial fishery. But when you start at a high trip limit, and that essentially is unlimited, that results in hitting your ACLs a lot quicker.

Rationing out the quota with more reasonable trip limits is probably something worth exploring. The accountability measures in the recreational fishery,

where we look at bag limit reductions to address overages. I think we've noticed with other recreational fisheries that relying on that tool alone doesn't always get you where you need to go, because in many cases, even with a high bag limit, you have to reduce that bag limit by a big number to get any impact.

Having something maybe a little less prescriptive, in terms of addressing overages, like we do with the recreational fisheries, is something that should be considered in the future. But we're not in a position to move forward on anything, until all these other things we talked about earlier get resolved.

CHAIR CIMINO: I think one thing that we can do, Emilie and I, is just keep track of this and we can provide updates to the Board as necessary, and then of course we will get us back on an agenda when needed.

CONSIDER THE FISHERY MANAGEMENT PLAN REVIEWS AND STATE COMPLIANCE FOR THE 2021 FISHING YEAR

CHAIR CIMINO: I think, unless there are any other hands on this, we can move into the next agenda item, which is Considering the Fishery Management Plan Reviews and State Compliance for the 2021 Fishing Year. I'll be turning this over to Emilie, who will do a presentation first on Spanish mackerel, and we'll pause after that. Then we'll move into cobia.

SPANISH MACKEREL FMP REVIEW

MS. FRANKE: I'll start with the Spanish mackerel FMP Review. We've already been discussing Spanish mackerel for a bit, so I'll keep it brief. But for the Interstate FMP for the Omnibus Amendment for both the recreational and commercial sector there is a 12-inch fork-length or a 14-inch total length size limit. For the recreational sector there is a 15-fish creel limit, and fish must be landed with the head and fins intact. Then for the commercial fishery, I already went over the trip limits, so we'll move on to the next slide.

As far as the status of the stock, as noted earlier, the 2012 assessment SEDAR 28 found this stock to be not overfished nor experiencing overfishing, and again this current stock assessment, SEDAR 78, completed in 2022 with a terminal year of 2020, is still undergoing additional revisions before being considered for use in management.

Moving on to the status of the fishery. As a reminder, all the landings in the FMP Review are calendar year landings, and also this FMP Review uses the current recalibrated MRIP estimates from the fishing effort survey. You know the previous FMP Reviews listed the state-by-state landings from the coastal household telephone survey.

However, with the intent of this new assessment to update to the FES based landings, the PRT agreed it was timely to switch these FMP reviews to reflect what MRIP currently reports for landings. The FMP Review does include this figure showing the comparison from the previous Coastal Household Telephone Survey, harvest estimates, which is the gray dash line, to the current FES based estimates, which is the solid black line.

Again, you can see those higher estimates with the new FES landings. As far as total landings in 2021 combined commercial and recreational. The combined landings were an estimated 14.6 million pounds, with the commercial fishery harvesting approximately 33 percent of that total, and the recreational fishery harvesting about 67 percent of that total. Again, based on the current MRIP estimates.

For the commercial sector specifically in 2021, landings were 4.75 million pounds of which 72 percent were landed in Florida, and 24 percent in North Carolina as the majority there. For the commercial sector, 2021 is one of only three years since 1995 with commercial landings over 4 million pounds.

On the recreational side, again according to the current MRIP estimates, recreational anglers harvested 8.6 million Spanish mackerel, or about

9.8 million pounds, which is the highest in the time series. Again, Florida and North Carolina account for the majority there, Florida with 69 percent and North Carolina with 15 percent by number of fish.

Then the number of recreational releases of Spanish mackerel have generally increased over time, reaching the highest in the time series in 2021 with 6 million releases. Again, as we heard earlier, there were some questions about the 2020 and '21 MRIP estimates, so the FMP Review will be updated with those revised MRIP estimates that John went over, once they've been updated in the MRIP database.

This figure here shows the commercial landings in blue and the recreational landings in gray. Again, you can see 2020 and '21 were the highest recreational landings in the time series, and commercial landings over the past few decades have largely been below 4 million pounds, except for a couple years, including 2021. Then as far as compliance in 2021 implementation. The PRT found no inconsistencies from the FMP, and again a note here that Rhode Island just declared interest in Spanish mackerel last year, so they are currently developing regulations through their state process for Spanish mackerel. Then finally to wrap up here, on the next slide for de minimis for Spanish mackerel. A state qualifies for de minimis if its previous three-year average combined commercial and rec landings is less than 1 percent of the coastwide average.

De minimis states are not required to implement any monitoring programs, although there are no specific monitoring requirements in the FMP. Rhode Island, New Jersey and Delaware have all requested de minimis, and they all do meet the requirements for de minimis. I'm happy to take any questions before I start the cobia FMP Review, if folks have any questions on Spanish mackerel.

CHAIR CIMINO: Okay, Shanna and then Lynn.

MS. MADSEN: If Lynn's question is about the FMP Review, I might let her take it first. No, different, okay. As the conversation has been developing around the table, before we get off of Spanish mackerel. My question was more a question of process. I think that you know a lot of us are asking questions about looking to characterize the fishery, gathering information about how the northern states are prosecuting their fisheries and things like that.

You float at the idea of forming a Technical Committee to start to potentially tackle some of these questions, and maybe we don't have specific tasks for that TC just yet. But it does sound like we're going to need to start to gather a lot of this information, in order to be able to really drill down on some of the questions that are coming out of this Board.

My question is, what do we need to do to form a TC, and do we potentially want to discuss that happening today, or going back to the states and starting to evaluate what our workloads look like, who could potentially sit on that, et cetera. I just don't know what the process looks like.

CHAIR CIMINO: Yes, that's a great question. We'll turn it over to Bob. I do think that you know now that we split this group out. I don't think we have any other TC that would seem appropriate to kind of lean on. We'll go to Bob.

EXECUITVE DIRECTOR BEAL: Yes, the process is actually very simple. If this Board wants a technical committee for Spanish mackerel they can make that decision, and then we would reach out to the states to populate the committee. Pretty straightforward, if that is what the Board wants to do. It doesn't have to go to the Policy Board or anything else, it's a Board decision at this level.

MS. FRANKE: Then maybe over the next few months, once we identify a potential TC member or a point of contact for each state. As staff, I can work with each contact to maybe for each state to submit some just general information on how their fisheries are prosecuted. We can come up with a couple questions for each state to fill out We will have sort of, I think someone mentioned sort of like

a fishery profile for the Commission states to get an idea of how the fisheries are prosecuted in each state. I'm seeing some head nods, so I can work over that over the next few months.

CHAIR CIMINO: Okay thanks, Lynn.

MS. FEGLEY: My question is resolved, thank you.

CHAIR CIMINO: Go ahead, Marty.

MR. MARTIN GARY: More maybe a question for Jason or Eric. I'm always intrigued by this northernmost distribution of fish when they're shifting or expanding. I was wondering if either of you could characterize what you're seeing up there in space and time, in terms of that species moving into your waters.

MR. ERIC REID: Well, thank you for the question. I just wanted to thank this Board for putting Rhode Island on this Board. I was really enthralled by a conversation about models that don't work and reallocation and all this other stuff. It's none of your business what happens in Rhode Island, because we're going to be out of here in another month.

To answer your question, Marty. I know outside of Narraganset Bay; I think it's still in state waters. There have been floating fish traps there forever, and they catch those fish pretty regular in the summertime. They are a lot of work to get in the water and get out of the water, and you can't find good help now, so I don't know how many of those traps are physically in the water now.

But I think the majority of our landings in the past is from that particular gear. But I'm sure the recreational sector catches them rod and reel, and there is some, you know gillnetting for bluefish and other things like that, which would certainly catch that fish as well. We don't land a lot of them, but you know. Where is Tom Fote: I've been around a long time, and back in 1979 it was nothing to have 3,000/4,000 pounds of Spanish mackerel in a fish trap.

CHAIR CIMINO: Eric, you asked. Tom has his hand up, so go ahead, Tom.

MR. THOMAS P. FOTE: Yes, I've seen over the years particular times that we had Spanish mackerel all over Jersey. Just when the warm water came up, we got them, and we're probably going to be getting a lot more with the change in temperature, and there are some looking forward to it. That maybe replace some of the fish that are moving north out of our area, but yes, it's interesting.

CHAIR CIMINO: Okay, I do want to continue to move us along, but I guess Bob mentioned it's simple, but I'm not sure. Do we need a formal motion, or we just we assume and it's the will of the Board?

MS. FRANKE: I don't think we need a motion to form a TC. Where it's the will of the Board we'll all move forward with that as staff.

CHAIR CIMINO: Okay, so we'll reach out, we'll send an e-mail looking for nominees for that. Okay, and we'll move on to cobia, and I'm sure we'll have some questions there, so go ahead, Emilie.

ATLANTIC COBIA FMP REVIEW

MS. FRANKE: I'll get in now to shifting gears to this Board's other species, which is the Atlantic stock of cobia. I'll go over the FMP Review here. As a reminder, Atlantic cobia are currently managed through Amendment 1 to the Interstate FMP approved in 2019, which transitioned Atlantic cobia to sole management by the Commission. Then also Addendum I was approved in 2020.

The total harvest quota for fishing years '21 through '23 is about 80,000 fish, which is allocated 96 percent to the recreational sector and 4 percent to the commercial sector. For the commercial sector, along with size limits and possession limits, commercial harvest from non de minimis states, which currently is Virginia, North Carolina and South Carolina, is tracked and reported to the Commission throughout the season, and the fishery closes if

commercial landings reach the specified commercial closure trigger.

Then 4 percent of the commercial quota portion is set aside for de minimis harvest. For the recreational fishery. Again, in addition to size and possession limits, the recreational quota is allocated to state harvest targets for non de minimis states. Every couple of years when specifications are set, these states evaluate their average landings against their harvest quota, and have to adjust measures if they are exceeding that target.

One percent of the recreational quota is set aside for de minimis harvest, and states that have recreational de minimis status can either adopt the same measures as the nearest non de minimis state, or they can simply adopt a 37-inch total length minimum size limit, and a one-fish per vessel limit.

As far as the status of the stock for Atlantic cobia. The most recent assessment was SEDAR 58, completed in 2020 with a terminal year of 2017. It found the stock was not overfished and overfishing was not occurring. The next SEDAR assessment is tentatively scheduled for 2025, with a terminal year of either 2023 or 2024.

As a reminder, the Atlantic cobia stock extends from Georgia northward. Cobia in Florida waters are considered part of the Gulf of Mexico stock, which is not managed by the Commission. For landings in 2021, total Atlantic cobia landings, both the commercial and recreational sectors combined were about 2.7 million pounds, with only 2.5 percent from the commercial sector, and over 97 percent from the recreational sector. Total 2021 landings were about a 13 percent increase from 2020.

Then on the commercial side, 2021 landings were 66,499 pounds, with Virginia, North Carolina harvesting the majority with about 44 percent each. Then the total landings from Virginia, North Carolina and South Carolina, so those non de minimis states, did not reach the closure trigger, so the fishery was open through the end of the year. Then for the recreational sector, in 2021 recreational landings were about 2.6 million pounds, or just under 91,000 fish by number. Virginia landed the majority with 63 percent, and North Carolina landed 12 percent. Looking at the whole time series from 1981 through 2021, average recreational harvest is about 1 million pounds per year. But as you can see more recently, landings have increased, so this most recent ten-year average is about 2.1 million pounds per year. Then as far as recreational releases, those have also generally increased. Over the last five years an average of 79 percent of the recreational catch were released alive. This is higher than the previous five-year average of about 61 percent.

This figure just shows the commercial and recreational landings in pounds. Again, you can see the commercial sector is pretty small there, at the bottom in orange, and then the rest is the recreational landings with some increases in recent years, as well as some fluctuations year to year. Then as far as 2021 implementation, the PRT found no inconsistencies from the FMP.

We did see a few regulation changes in 2021 based on Addendum I. After evaluating their previous landings against their new harvest target, Virginia implemented measures designed to reduce their recreational harvest by 42 percent, by lowering their vessel limit and shortening their season. Then North Carolina was able to liberalize their measures, and they increased the vessel limit for private anglers only for an additional month during the year.

Then for de minimis states, de minimis states changed their measures, again to either adopt the nearest non de minimis state, which for all of de minimis states is Virginia, or adopted the standard de minimis measure from the FMP. There are a couple of points here from the PRT regarding de minimis.

On the recreational side to qualify for de minimis a state's recreational harvest in two of the past three

years must be less than 1 percent of coastwide landings during that time. Rhode Island, New Jersey, Delaware, Maryland and Florida all requested de minimis status, and all these states met their requirement, except for Maryland.

In their compliance report, Maryland noted that given the variability in landings from year to year, after having 0 harvest in 2019 and being just over that 1 percent threshold in 2020. Maryland requested to continue under de minimis until this year's harvest can be evaluated. The PRT did discuss and agree with this rationale.

For commercial de minimis we had a similar situation. To qualify for commercial de minimis, landings for two of the last three years must be less than 2 percent of the annual landings during that time. We had Rhode Island, New Jersey, Delaware, Maryland, Georgia and Florida request commercial de minimis status, and all met the qualifications except for New Jersey.

In their compliance report New Jersey noted that their 2019 and 2021 landings were considered to be pretty anomalous, anomalously high, and also, they are tracking their current landings this year, and their current landings are less than 20 percent of what the landings were during those high years. New Jersey requested to continue under de minimis until this year's harvest can be evaluated, and again the PRT did agree with this rationale.

The PRT recommends the Board approve all de minimis requests, including Maryland and New Jersey. This sort of brought up a conversation at the PRT level that over the next few years you could see multiple states starting to exceed this de minimis threshold, especially if cobia landings in the Mid-Atlantic continue to increase. There are some potential management implications here, including you know if a state becomes non de minimis for commercial they would have to start conducting in-season monitoring and reporting of their commercial harvest.

Then on the recreational side, if a state becomes non de minimis you have to add that state to the calculation of recreational harvest targets. Then another thing is the current allocation regarding those recreational harvest targets is based only on data through 2015. That's another thing the PRT noted the Board may need to update, sort of in the coming years.

You know from the PRTs perspective, they recommend that as the Board is discussing new cobia specifications next year, and with the upcoming stock assessment. The Board should also discuss whether these updates to the recreational harvest targets and the allocations would be appropriate at that time as well.

Then just to wrap up. The final note from the PRT here is the PRT noted that New York's recent commercial cobia landings were 6.9 percent of coastwide landings in 2020, and 2.4 percent in '21. Based on those years, the PRT recommends New York declare an interest in Atlantic cobia, and update their regulations to meet de minimis.

I believe that New York has actually already started the process of updating their regulations to the de minimis requirements, and the PRT also noted that depending on future landing that as we mentioned before, this in-season monitoring may need to be required in some states. That's all I have for the FMP Review for cobia, a little bit more than Spanish mackerel. If you folks have questions, I'm happy to address those.

CHAIR CIMINO: We'll look for hands on questions. You know as we eat lunch today, we're going to have to think some big thoughts on what de minimis means for this species, because it's kind of baked in, since we have recreational harvest targets by state. As states move out of de minimis status there.

I'll tell you, Jim, if MRIP doesn't show decent numbers for New York and New Jersey this year, then I'm worried that survey is missing what's really happening on the water, because there was an

awful lot of talk about that. After we get through questions, we'll look for motions for approval for both species, but any questions? Go ahead, Malcolm.

DR. MALCOLM RHODES: This is probably just housekeeping, but Florida, since they are a member of this Board and requested recreational de minimis. Is that just kind of housekeeping?

MS. FRANKE: Yes, exactly. Florida is still required to submit a compliance report every year that basically says they harvested 0 cobia from the Atlantic migratory stock.

CHAIR CIMINO: Okay, oh go ahead.

MR. JAMES J. GILMORE, JR.: Just to give an update on New York. You know we're struggling with the data. In fact, it's like, are we going to get into declaring the fishery then declare out of the fishery and declare back in the fishery, the way the data is going. Just so, just an update of what New York is doing. We do have a rulemaking in process to adopt the current de minimis commercial and recreational harvest regulations that we've initiated another rulemaking so that if we exceed the coastwide TAC, whatever that we'll be able to shut the fishery down.

We've got the regulatory mechanisms in process. But 2021 the landings were over the 6-point whatever percent, and then this year, up to right now we've made it 200 pounds. The same thing on the recreational side. We had the last 10 years no landings from MRIP. This year we've got 3,500 fish we landed.

It's really all over the place. At this point we're not going to plan to declare in until we get some more stable data, because there are a lot of other factors going on, and I'm sure coming out of the COVID and everything is really making things kind of crazy. But we're going to keep monitoring it and once we get to that point, we'll clearly do what we need to do. Thanks.

CHAIR CIMINO: If no other hands with questions here we'll look for a motion to get these FMP Reviews approved. Lynn.

MS. FEGLEY: Mr. Chair, I would be happy to make that motion. I move to approve the Spanish Mackerel FMP Review for the 2021 fishing year, state compliance reports and de minimis requests for Rhode Island, New Jersey, and Delaware.

CHAIR CIMINO: Thank you for that, motion by Lynn Fegley, second Doug Haymans. Any discussion on the motion? Go ahead, Malcolm.

DR. RHODES: Just to kind of housekeeping. Do we need to add also approving the recommendation for the PRT looking into those de minimis issues? Is that part of this, or does that need to be added on to the motion?

MS. FRANKE: I think that's for cobia, and we don't need to add it to the motion. I think that's something that the Technical Committee and the PRT can discuss next year when looking into cobia specifications. But thanks for that.

CHAIR CIMINO: Any objection to the motion? No hands, good, we'll consider that approved by unanimous consent, and we'll look for a motion for the Cobia Review. Thanks, Doug, go ahead.

MR. DOUG HAYMANS: Mr. Chair, I move to approve the Atlantic Cobia FMP Review for the 2021 fishing year, state compliance reports and de minimis requests for Rhode Island, New Jersey, Delaware, Maryland, Georgia, and Florida.

CHAIR CIMINO: Great, thanks, second by Mel Bell. Any discussion? Great. Any objection to the motion? Seeing no objections, also approved by unanimous consent.

ADJOURNMENT

CHAIR CIMINO: If there is any other business to come before the Board you are not going to be very popular. But go ahead. No, great, so I'll look for a motion to adjourn. But before I do, I want to say

thank you again to Emilie and John for a great job.
Motion by Malcolm, all right, we are adjourned.

(Whereupon the meeting convened at 12:15 p.m.
on Tuesday November 8, 2022.)

MEMORANDUM

TO: **Coastal Pelagics Management Board**

FROM: **Emilie Franke and Chelsea Tuohy, Fishery Management Plan Coordinators**

DATE: **July 17, 2023**

SUBJECT: **Potential Timelines to Review State Recreational Allocations for Atlantic Cobia**

The Chair of the Coastal Pelagics Management Board (Board) added an agenda item for the Summer 2023 Board meeting to discuss potential timelines for reviewing state-by-state allocations of the recreational harvest quota for Atlantic cobia.

Under Amendment 1 (2019) to the Interstate Fishery Management Plan for Atlantic Migratory Group Cobia (FMP), percent allocations of the recreational harvest quota are based on states' percentages of coastwide historical landings in numbers of fish, derived as 50% of the 10-year average landings from 2006-2015 and 50% of the 5-year average landings from 2011-2015, with a 1% set-aside for landings in *de minimis* states (Table 1). When new fishery specifications are set, landings for each non-*de minimis* state is evaluated against that state's target as an average of annual landings for years with the same season and vessel limit. If a state's averaged recreational landings exceed its recreational harvest target, that state must adjust its recreational vessel limit or season to reduce harvest to achieve their harvest target. If a state's landings are below its target for two consecutive years, that state may extend seasons or increase vessel limits, if desired, to allow increased harvests to not exceed the harvest target.

In the FMP Review for Atlantic cobia for the 2021 Fishing Year, the Plan Review Team noted:

> *"…the current allocation of recreational quota to each state is based on landings data through only 2015, which may need to be updated to reflect more recent years. As the Board considers potential management action with the next set of specifications and with the next stock assessment, the PRT recommends the Board discuss whether updates to the state-by-state recreational harvest allocations are warranted."*

Reallocation of the recreational quota among states can be accomplished through an addendum to Amendment 1. One scenario that would require reallocation discussions is if a state exceeds the recreational *de minimis* threshold and loses their *de minimis* status; this would require reallocation to add that new non-*de minimis* state into allocation calculations.

If the Board would like to consider future management action to address state recreational allocations, staff have identified potential timelines and course of action outlined below, considering the upcoming stock assessment and specifications. The Board could pursue alternative timelines and course of action as desired. The next stock assessment for Atlantic

cobia is an update (i.e., operational assessment) scheduled for 2025 with potential to inform the 2026 or 2027 total harvest quota, depending on when the assessment is completed. The stock assessment schedule should be finalized by early 2024.

Potential Timeline 1: Prepare Recreational Allocation Action for 2026 Implementation to Coincide with Stock Assessment

- Summer-Fall 2023: Board tasks the Cobia Technical Committee (TC) with reviewing and summarizing state fishery landings relative to their current state harvest targets, including *de minimis* landings, and identifying relevant trends in state/regional landings.
- Mid-2024: Board initiates draft addendum to consider state recreational allocations, if desired based on TC report.
- Late 2024-Early 2025: Board approves draft addendum for public comment and states conduct public hearings.
- Mid-2025: Board considers selecting final measures and approval of the addendum for 2026 implementation.
- 2026: States implement new recreational management measures based on new recreational allocations/state harvest targets, and based on new total harvest quota if modified based on the stock assessment results (if assessment results are available).

Potential Timeline 2: Prepare Recreational Allocation Action for 2025 Implementation

- Summer 2023: Board tasks the Cobia TC with reviewing and summarizing state fishery landings relative to their current state harvest targets, including *de minimis* landings, and identifying relevant trends in state/regional landings.
- Early 2024: Board initiates draft addendum to consider state recreational allocations, if desired based on TC report.
- Mid-2024: Board approves draft addendum for public comment and states conduct public hearings.
- Late 2024: Board considers selecting final measures and approval of the addendum for 2025 implementation.
- 2025: States implement new recreational management measures based on new recreational allocations/state harvest targets.
- 2026: Potential change to total harvest quota based on stock assessment results, if available, and resulting change to state harvest targets and management measures based on new total harvest quota.

Table 1. Amendment 1 recreational allocation percentages for Atlantic cobia by state.

State	Allocation Percentage
Georgia	9.4%
South Carolina	12.1%
North Carolina	38.1%
Virginia	39.4%
De Minimis	1.0%
Total	100%

South Atlantic Spanish Mackerel

Section I: Introduction

May 2022

SEDAR
4055 Faber Place Drive, Suite 201 North Charleston, SC 29405

I. Introduction

1. SEDAR Process Description

SouthEast Data, Assessment, and Review (SEDAR) is a cooperative Fishery Management Council process initiated in 2002 to improve the quality and reliability of fishery stock assessments in the South Atlantic, Gulf of Mexico, and US Caribbean. The improved stock assessments from the SEDAR process provide higher quality information to address fishery management issues. SEDAR emphasizes constituent and stakeholder participation in assessment development, transparency in the assessment process, and a rigorous and independent scientific review of completed stock assessments.

SEDAR is managed by the Caribbean, Gulf of Mexico, and South Atlantic Regional Fishery Management Councils in coordination with NOAA Fisheries and the Atlantic and Gulf States Marine Fisheries Commissions. Oversight is provided by a Steering Committee composed of NOAA Fisheries representatives: Southeast Fisheries Science Center Director and the Southeast Regional Administrator; Regional Council representatives: Executive Directors and Chairs of the South Atlantic, Gulf of Mexico, and Caribbean Fishery Management Councils; a representative from the Highly Migratory Species Division of NOAA Fisheries; and Interstate Commission representatives: Executive Directors of the Atlantic States and Gulf States Marine Fisheries Commissions.

SEDAR 78 addressed the stock assessment for South Atlantic Spanish Mackerel. The assessment process consisted of a series of webinars held from May 2021 – March 2022. The Stock Assessment Report is organized into 2 sections. Section I –Introduction contains a brief description of the SEDAR Process, Assessment and Management Histories for the species of interest, and the management specifications requested by the Cooperator. Section II is the Assessment Process report. This section details the assessment model, as well as documents any data recommendations that arise for new data sets presented during this assessment process, or changes to data sets used previously.

The final Stock Assessment Reports (SAR) for South Atlantic Spanish Mackerel was disseminated to the public in May 2022. The Council's Scientific and Statistical Committee (SSC) will review the SAR for its stock. The SSCs are tasked with recommending whether the assessments represent Best Available Science, whether the results presented in the SARs are useful for providing management advice and developing fishing level recommendations for the Council. An SSC may request additional analyses be conducted or may use the information provided in the SAR as the basis for their Fishing Level Recommendations (e.g., Overfishing Limit and Acceptable Biological Catch). The South Atlantic Fishery Management Council's SSC will review the assessment at its Summer 2022 meeting, followed by the Council receiving the SAR at the Fall 2022 meeting. Documentation on SSC recommendations is not part of the SEDAR process and is handled through each Council

2. Atlantic Spanish Mackerel Management Overview

2.1 Fishery Management Plan and Amendments

The following summary describes only those management actions that likely affect Atlantic Spanish mackerel fisheries and harvest.

FMP Amendments affecting Atlantic Spanish mackerel:

Description of Action	Amendment	Effective Date
• Set MSY = OY = TAC (27,000,000 pounds). • Minimum size limit for is 12 inches FL, except for incidental catch allowance of 5% of the total catch by weight aboard.	Original FMP (SAFMC 1982) 48 FR 5274	February 4, 1983
• Provided framework procedure for pre-season adjustment of TAC. • TAC = 27,000,000 pounds • Limited purse seine harvest to 300,000 lbs in Atlantic and 300,000 lbs in Gulf • Minimum size limit for the commercial and recreational sectors are 12 inches FL or 14 inches TL.	Amendment 1 (SAFMC 1985) 50 FR 34846	August 28, 1985
• Revised MSY and clarified TAC must be set below the upper range of the ABC. • Recognized two migratory groups, Gulf and South Atlantic, with Dade/Monroe county line as the migratory group boundary. • TAC = 2,900,000 pounds • Established allocations for TAC, commercial (2,200,000 pounds, 76%) and recreational (700,000 pounds, 24%). • Established April 1 to March 31 fishing year. • Recreational bag limit of 4 fish in FL and 10 in NC, SC, and GA. • Charter boat permits were required.	Amendment 2 (SAFMC 1987) 52 FR 23836	June 25,1987

Description of Action	Amendment	Effective Date
• Prohibited drift gill nets for coastal pelagics and purse seines for the overfished group of mackerels.	Amendment 3 (SAFMC 1989) 54 FR 29561	July 13, 1989
• Reallocated Atlantic group Spanish mackerel equally between recreational and commercial fishermen. • TAC = 6,000,000	Amendment 4 (SAFMC 1989) 54 FR 38526	September 19, 1989
• Extended the management area for the Atlantic groups of mackerels through the Mid Atlantic Fishery Management Council's area of jurisdiction. • Revised the definition of overfishing. • Redefined recreational bag limits as daily limits, and removed the provision specifying that bag limit caught mackerel may be sold. • Size limit for Spanish mackerel is 12 " FL or 14" TL. • Bag limit is 4 fish off FL and 10 fish north of FL.	Amendment 5 (SAFMC 1990) 55 FR 29370	July 19, 1990

Description of Action	Amendment	Effective Date
• Specified rebuilding periods for overfished mackerel stocks. • Provided for commercial Atlantic Spanish mackerel possession limits. • In the northern zone, boats are restricted to possession limits of 3,500 pounds. In the southern zone trip limit are 1,500 pounds per vessel per day from April 1 to November 30. From December 1 until 80% of quota is taken: unlimited harvest on Monday, Wednesday, and Friday; 1,500 pounds per vessel per day on Tuesday and Thursday; 500 pounds per vessel per day on Saturday and Sunday. Trip limit 1,000 pounds per vessel per day when 80% of quota is reached. The adjusted quota for Spanish mackerel is 3,250,000 pounds. • Discontinued the reversion of the bag limit to 0 when the recreational quota is filled. • Modified the recreational fishing year to the calendar year, • Changed commercial permit requirements to allow qualification in one of three preceding years. • Changed all size limits to fork length only. Minimum size limit is 12 inches FL.	Amendment 6 (SAFMC 1992) 57 FR 58151	December 9, 1992
• Modified requirements for a king or Spanish mackerel permit. • Set the OY target to 40% static SPR for the Atlantic. • Modified the seasonal framework adjustment measures.	Amendment 8 (SAFMC 1994) 63 FR 10561	March 4, 1998
• Allowed the retention and sale of damaged, legal sized king and Spanish mackerel within established trip limits.	Amendment 9 (SAFMC 1998) 64 FR 16336	March 28, 2000

Description of Action	Amendment	Effective Date
• Established EFH in the South Atlantic	Amendment 10 (SAFMC 1998) 65 FR 37292	July 14, 2000
• Addressed Sustainable Fishery Act definitions.	Amendment 11 (SAFMC 1999)	December 1999
• Changed the fishing year for Atlantic group Spanish mackerel to March 1 through February 28/29.	Amendment 15 SAFMC (2004) 70 FR 39187	July 7, 2005
• Stock ACL= 5,690,000 pounds. • Commercial = 3,130,000 pounds and recreational = 2,560,000 pounds • Accountability Measures (AMs): Commercial sector to close when commercial ACL will be met; payback when total ACL is exceeded (and overfished). Recreational sector to lower bag limit, if necessary, if total ACL is also exceeded.	Amendment 18 SAFMC 2011 76 FR 82058	January 20, 2012
• Established coral HAPCs.	Amendment 19 in CE-BA1 SAFMC 2009 75 FR 35330	July 22, 2010

Description of Action	Amendment	Effective Date
• Prohibits king mackerel and Spanish mackerel bag limit sales in Atlantic except state permitted tournaments. • Removes income requirements for CMP permits.	Amendment 20A SAFMC 2013 79 FR 34246	July 16, 2014
• Recreational fishing measures in SC SMZs.	Amendment 21 in CE-BA 2 SAFMC 2011 76 FR 82183	January 30, 2012
• Requires weekly electronic reporting for headboats in South Atlantic.	Amendment 22 in HB reporting amendment SAFMC 2013 78 FR 78779	January 27, 2014
• King mackerel and Spanish mackerel dealers must get the universal permit. • Federal king mackerel and Spanish mackerel permit holders must sell to federal dealer. • Requires weekly electronic reporting for federal dealers.	Amendment 23 in Generic Dealer Amendment	August 7, 2014

Description of Action	Amendment	Effective Date
	SAFMC 2013 79 FR 19490	
• Set Northern (NC/SC line north) and Southern (NC/SC line south) zones and associated commercial quotas. • Northern Zone- 622,870 pounds; Southern Zone - 2,507,130 pounds.	Amendment 20B SAFMC 2014 80 FR 4216	March 1, 2015
• For hire reporting requirements.	Amendment 27 SAFMC 2017	January 4, 2021

SAFMC Regulatory Amendments affecting Atlantic Spanish mackerel:

Description of Action	Amendment	Effective Date
• Commercial allocation is 2,360,000 pounds and recreational allocation is 740,000 pounds. • Bag limits is 4 fish off FL and 10 fish north of FL.	52 FR 25012	July 2, 1987
• Final Rule on technical amendment that allows catch of Spanish mackerel under minimum size limit equal to 5% by weight of total catch or Spanish mackerel on board.	52 FR 36578	September 30, 1987
• Changed TAC to 4,000,000 pounds with 960,000 pounds allocated to the recreational sector and 3,040,000 pounds allocated to the commercial sector.	53 FR 25611	July 8, 1988
• TAC increased to 6,000,000 pounds with 1,440,000 pounds allocated to the recreational sector and 4,600,00 pounds allocated to the commercial sector.	54 FR 24920	April 1, 1989
• TAC changed to 5,000,000 pounds with 3,140,000 pounds allocated to the commercial sector and 1,860,000 pounds allocated to the recreational sector.	55 FR 25986	June 26, 1990
• TAC increased to 7,000,000 pounds with 3,500,000 pounds allocated to commercial sector and 3,500,000 pounds allocated to recreational sector. • Bag limit is 10 fish for areas north of FL and 5 fish for FL.	56 FR 29920	July 1, 1991
• Increased bag limit in Florida to that adopted by the state of FL but not to exceed 10 fish.	57 FR 33924	July 31, 1992

Description of Action	Amendment	Effective Date
• TAC increased to 9,000,000 with 4,500,000 pounds commercial and 4,500,000 pounds recreational. • The initial change in the trip limit occurs when 75% of the quota is met instead of 80%.	58 FR 40613	July 29, 1993
• TAC for Atlantic Spanish mackerel is increased to 9,200,000 pounds (4,600,000 pounds commercial and 4,600,000 pounds recreational).	59 FR 40509	April 1, 1994
• TAC increased to 9,400,000 pounds (4,700,000 pounds commercial and 4,700,000 pounds recreational).	60 FR 39698	April 1, 1995
• Reduced to 7,000,000 (3,500,000 pounds commercial and 3,500,000 pounds recreational). • Modify trip regime for commercial vessels off Florida east coast: Nov 1 rather than Dec 1 start for unlimited harvest season and increase the Saturday-Sunday daily trip limit from 500 to 1,500 pounds during that season and increase the daily trip limit from 1,000 to 1,500 pounds for all days of the week during the period that follows the unlimited season and continues until the adjusted quota is taken.	62 FR 23671	May 1, 1997
• Increased the TAC l to 8,000,000 pounds (4,000,000 pounds commercial and 4,000,000 pounds recreational).	62 FR 53278	April 1, 1997
• Decrease the TAC to 6,600,000 pounds and change the allocation from 50/50 to 55% commercial (3,630,000 pounds) and 45% recreational (2,970,000 pounds).	64 FR 45457	August 20, 1999

Description of Action	Amendment	Effective Date
• Increase TAC to 7,040,000 pounds with 3,870,000 pounds commercial and 3,170,000 pounds recreational. • The trip limit from April 1 to November 30 would be 3,500 lb; from December 1 until 75% of the adjusted quota is taken there would be no trip limit on Monday through Friday and on Saturday and Sunday the trip limit would be 1,500 lbs. • The recreational bag limit is increased from 10 to 1S5 fish per person per day. • MSY = 5.7-7.5 million pounds, Bmsy = 12.2-15.8, MSST = 8.5-11.1, MFMT = 0.38-0.48.	65 FR 41015	July 3, 2000
• Reduce Atlantic Spanish mackerel trip limit to 1,500 lbs per day from March 1, 2004 to March 31, 2004.	69 FR 9969	March 3, 2004
• Reduce trip limit for Atlantic Spanish mackerel to 1,500 lbs from February 1, 2005 to March 31, 2005.	70 FR 5569	February 3, 2005
• Reduce Atlantic Spanish mackerel trip limit to 1,500 lbs from February 5, 2007 to February 28, 2007.	72 FR 5345	February 6, 2007
• Change start date for commercial trip limit of the Atlantic Spanish mackerel in southern zone (off FL) to March 1.	73FR439	January 3, 2008
• Provisions for transfer at sea for gillnets when one set exceeds Spanish mackerel trip limit	Framework Action SAFMC 2013 79 FR 68802	December 19, 2014

Description of Action	Amendment	Effective Date
• ACL= 6,063,000 pounds with commercial 3,330,000 pounds and recreational 2,727,000 pounds.	FW Amendment 1 SAFMC 2014 79 FR 69058	December 22, 2014
• Trip limits in Southern Zone (SC, GA, FL): 3,500lbs until 75% adjusted quota is met, then 1,500lbs until adjusted quota is met and then 500lbs until the full quota is met.	FW Amendment 2 SAFMC 2014 80 FR 40936	August 13, 2015
• Permit restrictions: removes the restriction on fishing for, or retaining, the recreational bag and possession limits of king and Spanish mackerel on a vessel with a Federal commercial permit for king or Spanish mackerel when commercial harvest of king or Spanish mackerel in a zone or region is closed.	FW Amendment 5 SAFMC 2016 82 FR 35658	August 31, 2017

2.2 Emergency and Interim Rules (if any)

Description of Action	FRN	Effective Date
• Divided 3.716 million pounds quota into three areas with 1.869 million pounds going to the Atlantic. o The Atlantic boundary was bounded by the North Carolina/Virginia state line and a line directly east of the Dade/Monroe County, Florida boundary. • Established a recreational bag limit of 4-fish per trip and allowed sale of recreationally caught Spanish mackerel under the bag limit. • January 1, 1987 to March 31, 1987	52 FR 290	January 5, 1987
• 90-day extension of January 1, 1987 to March 31, 1987 emergency rule for Spanish mackerel.	52 FR 10762	April 3, 1987

2.3 Secretarial Amendments (if any)

None for Atlantic Spanish mackerel.

2.4 Control Date Notices (if any)

March 7, 2019: participants who enter the commercial sector after March 7, 2019, will not be assured of future access if a management regime that limits participation in the sector is prepared and implemented.

2.5 Management Program Specifications

Table 2.5.1. General Management Information

Species	Spanish mackerel (*Scomberomorus maculatus*)
Management Unit	Atlantic migratory group Spanish mackerel
Management Unit Definition	All waters from the intersection of New York, Connecticut, and Rhode Island to a line extending due east of the Miami-Dade/Monroe County line
Management Entity	South Atlantic Fishery Management Council (Note: Mid-Atlantic Council participates as voting member on South Atlantic Council's Mackerel Cobia Committee.)
Management Contacts SERO / Council	SAFMC: Christina Wiegand SERO: Mary Vara/Karla Gore
Current stock exploitation status	Not undergoing overfishing
Current stock biomass status	Not overfished

Table 2.5.2. Management Parameters

Criteria	South Atlantic – Current (SEDAR 28)		
	Definition	**Values**	**Units**
M	Average of Lorenzen M (if used)	0.35	Instantaneous natural mortality; per year
$F_{CURRENT}$	Geometric mean of full fishing mortality rates for 2009-2011 ($_{F2009-2011}$)	0.36	Per year
F_{TARGET}			
Yield at F_{TARGET} (equilibrium)			
F_{MSY}	F_{MSY}	0.69	Per year
B_{MSY}	Biomass at MSY	9548	Metric tons
R_{2012}			
R_{MSY}			
$R_{UNFISHED}$			
SSB_{2011}	Spawning stock biomass in 2011	4862	Metric tons
SSB_{MSY}	Spawning stock biomass at MSY	3266	Metric tons
MSST[1]	MSST = [(1-M) or 0.7 whichever is greater]*B_{MSY}	2127	Metric tons
MFMT	F_{MSY}	0.69	Per year
MSY	Yield at F_{MSY}	2750	Metric tons
OY	Yield at F_{OY}		
F_{OY}	F_{OY} = 65%, 75%, 85% F_{MSY}	65% F_{OY} = 0.449 75% F_{OY} = 0.518 85% F_{OY} = 0.587	
Exploitation Status	$F_{2009-2011}$/ F_{MSY}	0.526	
	F_{2011}/ F_{MSY}	0.521	
Biomass Status	SSB_{2011}/MSST	2.29	
	SSB_{2011}/ SSB_{MSY}	1.49	
Terminal F (2011)			
Terminal Biomass (2011) [1]			
Generation Time			
$T_{REBUILD}$ (if appropriate)			

Table 2.5.2. Management Parameters Continued				
Criteria	**South Atlantic – Proposed (SEDAR 78)**			
	Definition	**Base Run Values**	**Units**	**Median of Base Run MCBs**
M	Average of Lorenzen M (if used)			
$F_{CURRENT}$	Geometric mean of full fishing mortality rates for 2009-2011 ($F_{2009-2011}$)			
F_{TARGET}				
Yield at F_{TARGET} (equilibrium)				
F_{MSY}	F_{MSY}			
B_{MSY}[1]	Biomass at MSY			
R_{MSY}				
SSB				
SSB_{MSY}	Spawning stock biomass at MSY			
MSST[1]	MSST = [(1-M) or 0.7 whichever is greater]*B_{MSY}			
MFMT	F_{MSY}			
MSY	Yield at F_{MSY}			
OY	Yield at F_{OY}			
F_{OY}	F_{OY} = 65%, 75%, 85% F_{MSY}			
Exploitation Status				
Biomass Status[1]				
Terminal F	-			
Terminal Biomass [1]	-			
Generation Time	-			
$T_{REBUILD}$ (if appropriate)	-			

[1]Biomass values reported for management parameters and status determinations should be based on the biomass metric recommended through the Assessment process and SSC. This may be total, spawning stock or some measure thereof, and should be applied consistently in this table.

NOTE: "Proposed" columns are for indicating any definitions that may exist in FMPs or amendments that are currently under development and should therefore be evaluated in the current assessment. Please clarify whether landings parameters are 'landings' or 'catch' (Landings + Discard). If 'landings', please indicate how discards are addressed.

Table 2.5.3. Stock Rebuilding Information

None – Atlantic migratory group Spanish mackerel is not currently overfished.

Table 2.5.4. General Projection Specifications

South Atlantic

First Year of Management	2024/2025
Interim basis	ACL, if ACL is met. Average exploitation, if ACL is not met.
Projection Outputs	
Landings	Pounds and numbers
Discards	Pounds and numbers
Exploitation	F & Probability F>MFMT
Biomass (total or SSB, as appropriate)	SSB & Probability SSB>MSST (and Prob. SSB>SSB_{MSY} if under rebuilding plan)
Recruits	Number

Table 2.5.5. Base Run Projections Specifications. Long Term and Equilibrium conditions.

Criteria	Definition	If overfished	If overfishing	Neither overfished nor overfishing
Projection Span	Years	$T_{REBUILD}$	10	10
Projection Values	$F_{CURRENT}$	X	X	X
	F_{MSY}	X	X	X
	75% F_{MSY}	X	X	X
	$F_{REBUILD}$	X		
	F=0	X		

NOTE: Exploitation rates for projections may be based upon point estimates from the base run (current process) or upon the median of such values from the MCBs evaluation of uncertainty. The critical point is that the projections be based on the same criteria as the management specifications.

Table 2.5.6. P-star projections. Short term specifications for OFL and ABC recommendations. Additional P-star projections may be requested by the SSC once the ABC control rule is applied.

Basis	Value	Years to Project	P* applies to
P*	50%	Interim + 5	Probability of overfishing
P*	TBD[1]	Interim + 5	Probability of overfishing
Exploitation	F_{MSY}	Interim + 5	NA
Exploitation	75% of F_{MSY}	Interim + 5	NA

[1] To be determined by the SSC.

Table 2.5.7. Quota Calculation Details

If the stock is managed by quota, please provide the following information.

	Atlantic Spanish Mackerel
Current Acceptable Biological Catch (ABC) and Total Annual Catch Level (ACL) Value for Spanish Mackerel	ACL = ABC = OY ACL = 6,063,000 lbs.
Commercial ACL for Spanish Mackerel	ACL = 3,330,000 lbs.
Recreational ACL for Spanish Mackerel	ACL = 2,727,000 lbs.
Next Scheduled Quota Change	After assessment
Annual or averaged quota?	Annual
If averaged, number of years to average	-
Does the quota include bycatch/discard?	No

How is the quota calculated - conditioned upon exploitation or average landings?

Does the quota include bycatch/discard estimates? If so, what is the source of the bycatch/discard values? What are the bycatch/discard allowances?

The ABC, ACL, and recreational ACT values are based on landed catch only; discards are accounted for in specifying the ABC in terms of landed catch and not total mortality.

Are there additional details of which the analysts should be aware to properly determine quotas for this stock?

No.

2.6 Management and Regulatory Timeline

See attached tables below.

Table 2.5.8 Atlantic Migratory Group Spanish Mackerel Commercial Regulatory History prepared by: Christina Wiegand, SAFMC staff

Year	Quota (lbs ww)	ACL (lbs ww)	Days Open	Fishing Season	Reason for Closure	Season Start Date (first day implemented)	Season end Date (last day effective)	Size Limit	Size Limit Start Date	Size Limit End Date	Retention Limit (# fish)	Retention Limit Start Date	Retention Limit End Date

Notes:
1 Spanish mackerel managed as a single stock throughout the Gulf and South Atlantic.
2 Spanish mackerel managed as two migratory groups (Atlantic and Gulf migratory) from this point forward.
3 Management area extended from TX through NC to TX through NY.
4 Stock quota
5 Separate Northern (20%) and Southern Zone (80%) quotas.

Trip Limit Codes:
a Northern Zone (north of Florida/Georgia): 3,500
b Southern Zone (east Florida): 1,500 pounds per vessel per day from April 1 to November 30. From December 1 until 80% of quota is taken: unlimited harvest on Monday, Wednesday, and Friday; 1,500 pounds per vessel per day on Tuesday and Thursday; 500 pounds per vessel per day on Saturday and Sunday. Trip limit 1,000 pounds per vessel per day when 80% of quota is reached.
c Southern Zone (east Florida): 1,500 pounds per vessel per day from April 1 to November 30. From December 1 until 80% of quota is taken: unlimited harvest on Monday, Wednesday, and Friday; 1,500 pounds per vessel per day on Tuesday and Thursday; 500 pounds per vessel per day on Saturday and Sunday. Trip limit 1,000 pounds per vessel per day when 75% of quota is reached.
d Southern Zone (east Florida): 1,500 pounds per vessel per day from April 1 to OCtober 31. From November 1 until 80% of quota is taken: unlimited harvest on Monday, Wednesday, and Friday; 1,500 pounds per vessel per day on Tuesday and Thursday; 1,500 pounds per vessel per day on Saturday and Sunday. Trip limit 1,500 pounds per vessel per day when 75% of quota is reached.
e Southern Zone (east Florida): April 1 to November 30 would be 3,500 lb; from December 1 until 75% of the adjusted quota is taken there would be no trip limit on Monday through Friday and on Saturday and Sunday the trip limit would be 1,500 lbs.
f Northern Zone (north of North Carolina/South Carolina): 3,500
g Southern Zone (SC, GA, east FL): 3,500lbs until 75% adjusted quota is met, then 1,500lbs until adjusted quota is met and then 500lbs until the full quota is met.

Notes:

1 Spanish mackerel managed as a single stock throughout the Gulf and South Atlantic.

2 Spanish mackerel managed as two migratory groups (Atlantic and Gulf migratory) from this point forward.

3 Management area extended from TX through NC to TX through NY.

a Stock quota

2.7 State Regulatory History

Provided by the Atlantic States Marine Fisheries Commission

Table 2.2a. State Regulatory History – North Carolina and South Carolina as provided by the state management agencies.

Description of Action	State	Effective Date
1500 pounds max per day, land and sell aggregate king and Spanish mackerel combined	NC	08/04/80
2000 pounds max per day, land and sell aggregate king and Spanish mackerel combined	NC	10/01/81
3500 pounds max per day, land and sell aggregate king and Spanish mackerel combined	NC	10/01/82
Proclamation authority established to specify areas, seasons, quantity, means/methods, size limits	NC	12/01/87
Creel limit: 10 fish/person/fishing trip by hook and line	NC	6/15/88
Creel limit: 10 fish/person/fishing trip by hook and line unless person is in possession of Federal Permit to fish on Spanish mackerel quota. Charter boats with federal Coastal migratory Charter Permit shall not exceed 10 fish per person with more than 3 person on board including captain and mate.	NC	6/22/88
All coastal waters closed to harvest and retention of king and Spanish mackerel taken by any method. Proclamation expires 3/31/89	NC	3/7/89
Creel limit: 10 fish/person/dishing trip by hook and line unless person is in possession of Federal Permit to fish on Spanish mackerel quota. Charter boats with federal Coastal migratory Charter Permit shall not exceed 10 fish per person with more than 3 person on board including captain and mate. Creel limits do not apply to commercial fishermen using nets. Proclamation expires 3/31/90	NC	5/9/89
Creel limit: 10 fish/person/dishing trip by hook and line unless person is in possession of Federal Permit to fish on Spanish mackerel quota. Charter boats with federal Coastal migratory Charter Permit shall not exceed 10 fish per person with more than 3 person on board including captain and mate. Creel limits do not apply to commercial fishermen using nets.	NC	4/1/90
It is unlawful to have a purse gill net on board a vessel when taking or landing Spanish or King Mackerel.	NC	1/1/91
Commercial season closes, reopens 4/1/92	NC	1/5/92

Table 2.2a. State Regulatory History – North Carolina and South Carolina as provided by the state management agencies. Continued

12 inch FL minimum size.	NC	2/15/94
Creel limit: 10 fish/person/dishing trip by hook and line unless person is in possession of Federal Permit to fish on Spanish mackerel quota. Charter boats with federal Coastal migratory Charter Permit shall not exceed 10 fish per person with more than 3 person on board including captain and mate. Creel limits do not apply to commercial fishermen using nets except as specified by NCAC 3M/.0301.	NC	2/15/94
Proclamation authority for hook and line deleted. Entered into rule: Creel limit: 10 fish/person/dishing trip by hook and line unless person is in possession of Federal Permit to fish on Spanish mackerel quota. Charter boats with federal Coastal migratory Charter Permit shall not exceed 10 fish per person with more than 3 person on board including captain and mate	NC	3/1/96
Temporary rule change: Recreational purpose wording added and commercial gear working changed to commercial fishing operation. 12 inch minimum size Creel limit: 10 fish per person per day if taken by hook & line or for recreational purpose Holders of valid federal permits may exceed creel limit. Charterboats with valid federal permits shall not exceed 10 fish per person while fishing with more than 3 persons on board including captain and mate.	NC	7/1/99
It is unlawful to possess more than 15 Spanish mackerel per person per day taken for recreational purposes. It is unlawful to possess more than 15 Spanish mackerel per person per day in the Atlantic Ocean beyond three miles in a commercial fishing operation except for persons holding a valid National Marine Fisheries Service Spanish Mackerel Commercial Vessel Permit.	NC	4/1/01
Full consistency with federal regulations	SC	06/88-2007

Table 2.2b. State Regulatory History - North Carolina through Florida for Spanish mackerel as of 1990 as recorded in the Fishery Management Plan for Spanish Mackerel, Fishery Management Report No. 18, Atlantic States Marine Fisheries Commission, November 1990.

State	Bag Limit	Size Limit	Other
NC	10 fish	none	3,500 lb commercial trip limit
SC	10 fish	12" FL min.	Season closes with EEZ closure
GA	10 fish	12" FL min.	Recreational season open 3/16-11/30; 5% size tolerance by weight on trawlers
FL	5 fish	12" FL min.	1,850,000 lb quota for power assisted gill nets; season: Dec 15-Oct31. 205,000lb quota for all other forms of commercial fishing gears; season: Nov 1-Oct 31. 3 1/2 inch minimum stretched mesh.

Table 2.2c. State Regulatory History - New York through Florida, for Spanish Mackerel at specific times as taken from annual ASMFC FMP Reviews for Spanish Mackerel.

As of December 1995

State	Bag Limit	Size Limit	Other
NJ	10 fish	14" TL min.	
DE	10 fish	14" TL min.	
MD	10 fish	14" TL min.	Declaration allowing regulation through framework. Gill net mesh sizes for Chesapeake Bay.
VA	10 fish	14" TL min.	Size limit exemption for pound net fishery; closure when quota reached; 3500 lb trip limit.
NC	10 fish	12" FL min.	3,500 lb commercial trip limit (Spanish and king mackerel combined); finfish excluder devices required in shrimp trawls. Purse gill net prohibition.
SC	10 fish	12" FL min.	3,500 lb commercial trip limit tracking by reference the federal FMP.
GA	10 fish	12" FL min.	Season closed December 1 - March 15.
FL	10 fish	12" FL min.	3 1/2 inch minimum mesh size, 600 yd. maximum length net. Commercial daily trip limits: 1,500 lb April 1 - November 30; December 1 until 75% of adjusted quota reached-unlimited harvest on Monday, Wednesday, and Friday; 1,500 lb per vessel per day on Tuesday and Thursday; 500 lb per vessel per day on Saturday and Sunday; >75% adjusted quota until quota fulfilled-1,000 lb per vessel per day; >100% of adjusted quota-500 lb per vessel per day.

As of September 1998

State	Bag Limit	Size Limit	Other
NY	10 fish	14" TL min.	3,500 lb. commercial trip limit
NJ	10 fish	14" TL min	
DE	10 fish	14" TL min

NY	14" TL, 15 fish	14" TL. 3,500 lb trip limit.	*North Carolina*
NJ	14" TL, 10 fish	14" TL. 3,500 lb trip limit.	One proclamation was issued under rule 15A NCAC 03M .0512 to remain in compliance with the Atlantic States Marine Fishery Commission. Addendum I to the Omnibus Amendment establishes a pilot program that would allow states to reduce the Spanish mackerel minimum size limit for the commercial pound net fishery to 11 ½ inches during the summer months of July through September. The measure is intended to reduce waste of these shorter fish, which are discarded dead in the summer months, by converting them to landed fish that will be counted against the quota. The Division issued a proclamation suspending the 12-inch fork length size limit and adopting the 11 ½ inch fork length size limit in the commercial pound net fishery from July 4, 2016 to September 30, 2016.

All information included in the previous tables were pulled from the annual state FMP compliance reports (NY-FL), and reported in annual ASMFC FMP Reviews for Spanish Mackerel.

3. Assessment History

Full stock assessments of the south Atlantic Spanish mackerel were conducted by Powers et al. (1996), Legault et al. (1998) and the Sustainable Fisheries Division (2003 and 2007). Historically, the Mackerel Stock Assessment Panel (MSAP) met regularly to oversee and review these assessments and provide advice to the SAFMC and GMFMC.

The most recent full stock assessment for south Atlantic Spanish mackerel was conducted in 2007 in SEDAR 17 using three separate models: ASPIC , BAM, and SRA. The SEDAR 17 Review Panel was presented with a base model using BAM, as neither ASPIC nor SRA were considered appropriate to produce standalone representations of the stock dynamics. The BAM was used with the following as input data: five fisheries and their corresponding age and length compositions, three fishery discard series, shrimp bycatch, seven fishery-dependent indices, two fishery-independent indices, one combined index and discard mortality rates. The base run was configured as a two sex model incorporating differences in growth by sex. Natural mortality was constant through time, but varied by age. The panel did not accept the base model of the assessment as appropriate for making biomass determinations. They concluded that there is an overall increasing trend in biomass, but that a biomass decline was observed from 2003 to 2007. The panel noted that the fishing mortality at the terminal year of the model (2007) did not seem to be inhibiting stock growth. Although the panel did not accept the model conclusions regarding biomass, they accepted model results that the stock was not undergoing overfishing. The panel remarked that the major issues with the assessment were the shrimp bycatch uncertainty, the historical recreational catch derivation, and the lack of an objective likelihood weighting method. The assessment previous to SEDAR 17 was in 2003 through the Mackerel Stock Assessment
Panel (MSAP), which included data through the 2001/2002 fishing year (Sustainable Fisheries Division 2003). Estimated fishing mortality for Atlantic group Spanish mackerel was found to be below FMSY and FOY since 1995. Estimated stock abundance had increased since 1995 and was found to be at a high for the analysis period. Probabilities that the Spanish mackerel was overfished were less than 1% and that overfishing had occurred in the most recent fishing year of the assessment were 3%; therefore, the MSAP concluded that south Atlantic Spanish mackerel was not overfished and overfishing did not occur in 2002/2003.

SEDAR-28 (SEDAR-28, 2012) was a benchmark assessment using the Beaufort Assessment Model (BAM) with data through 2011. BAM is an integrated catch-age model, and is customizable to the multiple data sources available (Williams and Shertzer, 2015). A surplus production model implemented with the ASPIC software (Prager 1994, Prager 2004 was used as a complement for comparison purposes. Based on the assessment provided from the BAM, the Review Panel concluded

that the stock was not overfished and not undergoing overfishing. The stock biomass status in the base run from the BAM was estimated to be SSB2011/MSST=2.29. The level of fishing (exploitation rate) was F2009-2011/FMSY = 0.526, with F2011/FMSY = 0.521. The qualitative results on terminal stock status were similar across presented sensitivity runs, indicating that the stock status results were robust given the provided data and can be used for management. The outcomes of sensitivity analyses done with BAM were in general agreement with those of the Monte Carlo Bootstrap Ensemble analysis (an additional way to examine uncertainty) in BAM. In general, stock status results from ASPIC were qualitatively similar to those from BAM.

1. Introduction

This operational assessment evaluated the stock of Spanish mackerel (*Scomberomorus maculatus*) in the South Atlantic region of the southeastern United States. The primary objectives were to update and improve the 2012 SEDAR 28 benchmark assessment of and to conduct new stock projections. Using data through 2011, SEDAR 28 had indicated that the stock was not overfished and not undergoing overfishing. For this SEDAR 78 assessment, data compilation and assessment methods were guided by methodology of SEDAR 28, as well as by current SEDAR practices and recommendations by the SEDAR 28 review panel. The assessment period is 1986–2020.

Available data on this stock included indices of abundance, landings, discards, and samples of annual age compositions from fishery dependent sources. Three indices of abundance were fitted by the model: one from the Florida commercial trip tickets, one from the recreational MRIP intercepts for harvested fish, and one from the age-0 SEAMAP Coastal Trawl Survey. Data on landings and discards were modeled from five distinct fleets and two bycatch series: commercial handline, commercial gillnet, commercial pound net, commercial cast net, and general recreational (shore, private and charter modes) landings and discards.

The primary model used in SEDAR 28—and the one updated here—was the Beaufort Assessment Model (BAM), an integrated statistical catch-age formulation. A base run of BAM was configured to provide point estimates of key management quantities, such as stock and fishery status. Uncertainty in estimates from the base run was evaluated through a mixed Monte Carlo/Bootstrap Ensemble (MCBE) procedure. Median values from the uncertainty analysis are also provided. Sensitivity runs were developed to evaluate the model at the MCBE bounds for fixed natural mortality, steepness, and general recreational discard mortality parameters as well as exclusion of the commercial handline index.

The assessment estimated that spawning stock has fluctuated on a near-decadal cycle near or above the minimum stock size threshold (MSST) level. The base-run estimate of terminal (2020) spawning stock was above the MSST ($SSB_{2020}/MSST = 1.40$), as was the median estimate from the MCBE ($SSB_{2020}/MSST = 1.42$). The estimated fishing rate has been at or below the maximum fishing mortality threshold (MFMT), represented by F_{MSY} with the exception of the terminal year (2020). The terminal estimate, which is based on a three-year geometric mean, was below F_{MSY} in the base run ($F_{2018–2020}/ F_{MSY} = 0.77$) and in the median of the MCBE ($F_{2018–2020}/ F_{MSY} = 0.74$). Thus, this assessment indicated that the stock is not experiencing overfishing. However, this result requires caution: if the overfishing rate of 2020 continued in 2021, the geometric mean would indicate overfishing.

The MCBE analysis illustrated that these estimates of stock and fishery status are robust. Of all MCBE runs, 92.6% were in agreement that the stock is not overfished, and 90.0% were in agreement that overfishing is not occurring. Although qualitative results were robust, the primary sources of uncertainty in quantitative results (i.e., degree of overfishing or overfished) was natural mortality and steepness.

The estimated trends of this operational assessment were quite similar to those from the SEDAR28 benchmark. However, the two assessments did show some differences in results, which was not surprising given several modifications made to both the data and the model (described throughout the report). The two assessments showed similar stock status between 1986 and 2011, the terminal year of SEDAR28. Since then, SEDAR 78 indicated that the Spanish mackerel stock has fluctuated near the MSY reference point.

1.1 Workshop Time and Place

The SEDAR 78 South Atlantic Spanish Mackerel assessment took place over a series of webinars held from May 2021 to March 2022.

1.2 Terms of Reference

1. Update the approved SEDAR 28 Spanish Mackerel model with data through 2020. Apply the current BAM configuration incorporating approved improvements developed since SEDAR 28.
2. Evaluate and document the following specific changes in input data or deviations from the benchmark model.
    - Update growth and reproductive models if additional samples are available for fish below 275 mm
    - If available, include any improved information on steepness for similar pelagic species.
    - Evaluate data uncertainty with respect to the recreational landings
    - Calculate different F metrics (in addition to apical F) (to address shifts in the age of apical F towards the end of the assessment time series).
3. Document any changes or corrections made to model and input datasets and provide updated input data tables. Provide commercial and recreational landings and discards in pounds and numbers.
4. Update model parameter estimates and their variances, model uncertainties, estimates of stock status and management benchmarks, and provide the probability of overfishing occurring at specified future harvest and exploitation levels.
5. Convene a working group including SSC representatives to meet via webinar, as needed to review model development relative to terms of reference 1 through 4.
6. Develop a stock assessment report to address these ToRs and fully document the input data, methods, and results.

1.5 Statements Addressing Each Terms of Reference

Note: Original ToRs are in normal font. Statements addressing ToRs are in italics.

1. Update the approved SEDAR 28 Spanish mackerel model with data through 2020. Apply the current BAM configuration incorporating approved improvements developed since SEDAR 28.

SEDAR78 applied the current BAM configuration. The assessment model structure and data sources were very similar to those used in SEDAR28. Important modifications, such as selectivity functions were investigated through likelihood profiles and visual comparisons of model fit to the data. The decision to remove sex-specific growth and selectivity and modify the start year for the model were evaluated and shown to improve model performance.

2. Evaluate and document the following specific changes in input data or deviations from the benchmark model.

    - Update growth and reproductive models if additional samples are available for fish below 275 mm.
    - If available, include any improved information on steepness for similar pelagic species.
    - Evaluate data uncertainty with respect to the recreational landings.
    - Calculate different F metrics (in addition to apical F) (to address shifts in the age of apical F towards the end of the assessment time series).

All the above bullet points were addressed. Growth models were developed with increased age-0 samples primarily from the SEAMAP Coastal Trawl Survey. There was very limited reproduction information. There was no new information on steepness that could be applied in this assessment. Likelihood profiles on steepness had similar results to SEDAR28. Uncertainty in recreational landings was presented in the associated working paper. Years with large increases, such as 2020, were evaluated and discussed in greater detail. The spawning potential ratio conditional on annual F and exploitation rates were examined as additional F metrics.

3. Document any changes or corrections made to model and input datasets and provide updated input data tables. Provide commercial and recreational landings and discards in pounds and numbers.

Changes to data and model are documented in the report, along with tables of updated data input and removals in both pounds and numbers.

4. Update model parameter estimates and their variances, model uncertainties, estimates of stock status and management benchmarks, and provide the probability of overfishing occurring at specified future harvest and exploitation levels.

All of these key estimates and outputs are documented in the report.

5. Convene a working group including SAFMC Science and Statistical Committee representatives to meet via webinar, as needed to review model development relative to terms of reference 1 through 4.

The SEDAR78 panel did not suggest working groups were needed during model development.

6. Develop a stock assessment report to address these TORs and fully document the input data, methods, and results.

Please see this report.

2 Data Review and Update

The input data for this assessment are described below, with focus on modifications from the SEDAR 28 benchmark assessment.

2.1 Data Review

In this operational assessment, the Beaufort assessment model (BAM) was fitted to data sources developed during the SEDAR 78 process, evaluated over several webinars. These data include updates to SEDAR 78 data, where appropriate, which are highlighted below.

Model inputs used in SEDAR 28 and SEDAR 78

- Life history: Meristics, population growth, fishery dependent size at age, female size at age, female maturity, proportion female, age-dependent natural mortality
- Landings and discards: Commercial handline, gillnet, pound net, and cast net combined landings and discards, shrimp bycatch, general recreational landings and discards
- Indices of abundance: Commercial handline, MRIP, SEAMAP YOY [1]
- Age compositions: Commercial handline, gillnet, pound net, and cast net landings, and general recreational landings
- Other: General recreational discard mortality

Updated data sources in SEDAR 78

- Life history: Population growth, fishery dependent size at age, female size at age, age-dependent natural mortality
- Landings and discards: Commercial handline, gillnet, pound net, and cast net combined landings and discards, shrimp bycatch, general recreational landings and discards
- Indices of abundance: Commercial handline, MRIP, SEAMAP YOY
- Age compositions: Commercial handline, gillnet, pound net, cast net, and general recreational

2.2 Data Update

2.3 Life History

A total of 32,348 (1986 — 2020) Spanish mackerel ages were prepared for SEDAR 78. Several data sources reevaluated age sample information for the entire time series. Gear identification was improved for some fishery dependent samples and deemed unreliable for others. In addition, many more YOY samples were collected since SEDAR 28 primarily from the SEAMAP Coastal Trawl Survey (see SCDNR sample sizes, mostly age–0 and age–1 fish, in SEDAR78-WP08 (2021)).

Estimates of the von Bertalanffy growth parameters updated for the population as a whole ($L_\infty = 582.5$ mm, $K = 0.6$ yr^{-1}, and $t_0 = -0.5$ yr), the female population ($L_\infty = 610.1$ mm, $K = 0.62$ yr^{-1}, and $t_0 = -0.5$ yr), and the fished

[1] Abbreviations and acronyms used in this report are defined in Appendix A

population (L_∞ = 680.4 mm, K = 0.2 yr^{-1}, and t_0 = −2.77 yr). For the population as a whole and the female population, the t_0 parameter was fixed, samples were weighted by the inverse of the number of samples at age, and a correction was applied for bias from fishery dependent samples (Diaz et al. 2004). Length at age for all growth models are given in Table 1.

Age–based (Lorenzen 1996) natural mortality estimates were updated using new population growth parameters for SEDAR 78. As in SEDAR28, the cumulative survival of age 2+ based on a point estimate of natural mortality, 0.35, was used to scale the age–based estimates of natural mortality (Table 1).

2.4 Landings

The fleet structure used in SEDAR 78 was the same as that of SEDAR 28, including commercial handline, gill net, cast net, pound net, and general recreational (including estimates of headboat and MRIP private, charter, and shore–based landings). General recreational landings and discards were estimated using the current MRIP methodology (SEDAR78-WP03 2021). The commercial estimated landings were input as whole pounds. The commercial "other" estimated landings were divided between commercial gears based on the annual proportion of each (Table 2). General recreational landings were input in numbers (thousands).

2.5 Discards and Bycatch

Discards were estimated for commercial gill net, handline, and trolling (included with handline) in numbers (SEDAR78-WP11 2021). The commercial discards were converted to pounds based on the average weight of fish less than the 12 inch size limit weighted by the observed proportion in the overall length composition. These minor removals were then combined with their respective catch time series. General recreational discards were estimated in numbers and were modeled separately as in SEDAR 28 (Table 2, SEDAR78-WP03 (2021)). Spanish mackerel are observed in the shrimp trawl fishery in the South Atlantic. Shrimp bycatch estimates were developed using methods consistent with SEDAR 28 (SEDAR78-WP04 2021). General recreational discards and shrimp bycatch were developed in numbers as input to the model (Table 2).

2.6 Indices of Abundance

Two fishery dependent indices and one fishery independent recruitment index were developed for SEDAR 78. The general recreational MRIP index and associated CVs for harvested fish were updated through 2020 (SEDAR78-WP09 2021). This index was later truncated to start in 1986 and renormalized to its mean to coincide with the start year of the model. An index from Florida commercial handline trip ticket records was developed (SEDAR78-WP12 2021). A recruitment index of age–0 fish from the SEAMAP Coastal Trawl Survey was formulated for 1989–2019 (SEDAR78-WP01 2021; SEDAR78-WP02 2021). All finalized indices for potential use in the Spanish mackerel stock assessment and associated CVs are in Table 3.

2.7 Length Composition

As in SEDAR 28, length data were not used to inform the model. However, length compositions can be used to remove bias in samples collected for age determination. Only the commercial gillnet collections had adequate samples to develop weighted length composition data (SEDAR78-WP05 2021). This composition was developed solely to weight the commercial gillnet age composition.

2.8 Age Composition

Age data were available from the commercial handline, pound net, gill net, cast net and general recreational sampling programs. Nominal age compositions were developed for Spanish mackerel except commercial gillnet which was weighted by the length composition (Chih 2009; SEDAR78-WP05 2021). Ages greater than 10 were pooled to age 10 creating a plus group (age 10+; Tables 4–8).

3 Stock Assessment Methods

3.1 Overview

This operational assessment updated the primary model applied in SEDAR28 (2012), an integrated model implemented using the BAM software (Williams and Shertzer 2015). BAM applies a statistical catch-age formulation, coded in AD Model Builder (Fournier et al. 2012). BAM is referred to as an integrated model because it uses multiple data sources relevant to population and fishery dynamics (e.g. removals, length and age compositions, and indices of abundance) in a single framework. In essence, the catch-age model simulates a population forward in time while including fishing processes (Quinn and Deriso 1999; Shertzer et al. 2008). The model is similar in structure to Stock Synthesis (Methot and Wetzel 2013) and other stock assessment models used in the United States (Dichmont et al. 2016; Li et al. 2021). Versions of BAM have been used in previous SEDAR assessments of reef fishes in the U.S. South Atlantic, such as black sea bass, blueline tilefish, gag, greater amberjack, red grouper, red porgy, snowy grouper, tilefish, and vermilion snapper, as well as in the previous SEDAR assessments of Spanish mackerel (SEDAR17 2008; SEDAR28 2012). The primary model in this assessment was a statistical catch-age model (Quinn and Deriso 1999), implemented with the AD Model Builder software (ADMB Foundation 2012). Statistical catch-age models share many attributes with ADAPT-style tuned and untuned VPAs.

3.2 Data Sources

The catch-age model was fit to data from one fishery independent recruitment index, two fishery dependent indices, estimates of bycatch in the shrimp fishery, and to data from each of the five primary fisheries on southeastern U.S. Spanish mackerel: commercial gill net, commercial pound net, commercial cast net, commercial handlines (including hook & line, trolling, and electric reels), and general recreational (including headboat). These data included annual landings by fishery (in total weight for commercial and in numbers for general recreational and shrimp bycatch), annual discards from the general recreational sector, and annual age composition of landings by fishery. Discards from the commercial fisheries were added to landings as they were not a large enough proportion of total catch to model separately (Table 2). Data on annual discard mortalities were not available, but an overall discard mortality rate of 0.2 for the general recreational sector was applied to total discards as per the recommendation of the SEDAR 28 DW. All shrimp bycatch was assumed dead.

3.3 Model Configuration

The assessment time period was 1986–2020. The initial year was modified from SEDAR 28 to begin when adequate information was available to inform the initial age structure of the population and fishing rates. These values were assumed and fixed in SEDAR 28 and age compositions are not available until 1990. SEDAR 28 had to make assumptions about population age structure and fishing mortality to initialize the model in 1950. The terminal year extended from 2012 to 2020. A general description of the assessment model follows.

3.4 Stock Dynamics

In the assessment model, new biomass was acquired through growth and recruitment, while abundance of existing cohorts experienced mortality from fishing and natural sources. The population was assumed closed to immigration and emigration. The model included age classes $0-10^{+}$, where the oldest age class 10^{+} allowed for the accumulation of fish (i.e., plus group).

3.5 Initialization

Initial (1986) numbers at age assumed the stable age structure computed from expected recruitment and the initial, age-specific total mortality rate. That initial mortality was the sum of natural mortality and fishing mortality, where fishing mortality was the product of an initial fishing rate (F_{init}) and F-weighted selectivity based on starting year landings. The initial fishing rate was estimated using a starting value of $F_{\text{init}} = 0.5$ and no prior. The initial recruitment in 1986 was estimated.

3.6 Natural Mortality Rate

The natural mortality rate (M) was assumed constant over time, but decreasing with age. The form of M as a function of age was based on Lorenzen (1996). The Lorenzen (1996) approach inversely relates the natural mortality at age to mean weight at age W_a by the power function $\mathrm{M}_a{=}\alpha W_a^{\beta}$, where α is a scale parameter and β is a shape parameter. Lorenzen (1996) provided point estimates of α and β for oceanic fishes, which were used for this assessment. As in previous SEDAR assessments, the age-dependent estimates of M_a were rescaled to provide the same fraction of fish surviving from age 2 through the oldest observed age (12 yr) as would occur with constant $M = 0.35$, which is consistent with the findings of Hoenig (1983) and discussed in Hewitt and Hoenig (2005). The scaled Lorenzen estimator has become common in SEDAR assessments as the most reliable approach to infer age-dependent natural mortality.

3.7 Growth

Mean size at age of the population, female population, and fishery removals under a 12-inch size limit (fork length, FL) were modeled with the von Bertalanffy equation, and weight at age (whole weight, WW) was modeled as a function of FL (Figure 1, Table 1). Parameters of growth and conversions (FL-WW) were treated as input to the assessment model.

3.8 Female Maturity and Sex Ratio

Female maturity was modeled with a logistic function; parameters for this model and a vector of maturity at age were provided by the SEDAR 28 DW and treated as input to the assessment model (Table 1). The sex ratio was assumed to be 50:50, as in SEDAR 28.

3.9 Spawning Biomass

Spawning biomass (in units of mt) was modeled as the mature female biomass. It was computed each year from number at age when spawning peaks. For Spanish mackerel, peak spawning was considered to occur on June 1^{st}.

3.10 Recruitment

Recruitment was predicted from spawning biomass using a Beverton–Holt spawner-recruit model. These stock-recruit parameters are median-unbiased values (Li et al. 2021). For all years in the model (1986–2020), estimated recruitment was conditioned on the Beverton–Holt model. Steepness was fixed at 0.75 for the base run.

3.11 Landings

Time series of landing from five fisheries were modeled: commercial handlines, commercial gillnet, commercial pound net, commercial cast net, and general recreational (including headboat). Landings were modeled via the Baranov catch equation (Baranov 1918), in units of 1000 lb whole weight for commercial fisheries and in units of 1000 fish for the general recreational fishery and bycatch.

3.12 Discards

Starting in 1986 with the implementation of size-limit regulations, time series of discard mortalities (in units of 1000 fish) were available for commercial handline and gill net fisheries. The magnitude of the commercial discards was trivial in comparison to the landings. As a result, the commercial discards were included with the landings rather than model the discards separately. General recreational discards were modeled seperately and decremented by the discard mortality rate (0.2) determined in SEDAR 28. As with landings, discard mortalities were modeled via the Baranov catch equation (Baranov 1918), which required estimates of discard selectivities (described below) and release mortality rates.

3.13 Bycatch

Spanish mackerel are observed in the shrimp trawl fishery in the South Atlantic. However, the observer coverage is extremely sparse and effort data are questionable. Estimates were provided by the data workshop that assumed a constant relationship over time between the rate of bycatch and effort by state (SEDAR78-WP04 2021). Bycatch was modeled via the Baranov catch equation (Baranov 1918), assuming that only age 0 fish and a small proportion of age 1 fish were selected with 100% mortality.

3.14 Fishing

For each time series of landings and discard mortalities, a separate full fishing mortality rate (F) was estimated. Age-specific rates were then computed as the product of full F and selectivity at age. The across-fleet annual F was represented by apical F, computed as the maximum of F at age summed across fleets.

3.15 Selectivities

Selectivity curves applied to landings were estimated using a parametric approach. This approach applies plausible structure on the shape of the curves, and achieves greater parsimony than occurs with unique parameters for each age. Flat-topped selectivities were modeled as a two-parameter logistic function (logistic). Dome-shaped selectivities were modeled by combining two logistic functions: a two-parameter logistic function to describe the ascending limb of the curve, and a two-parameter logistic function to describe the descending limb (double–logistic). Another type of domed–shaped selectivity allowed for a freely estimated logit parameter for age–0, a fixed peak at age–1, and an exponential decline for age 2^+ (logit–exponential).

To model landings, this assessment applied flat-topped selectivity for the commercial handline and cast net fleets, both pooled over years due to small sample sizes. Dome-shaped selectivity was used to model commercial gillnet landings. Commercial pound net and general recreational fleets were modeled using the logit–exponential selectivity. The approach to modeling each of these fleets was modified from decisions in SEDAR 28 to improve model fit and stability and based on total likelihood or likelihood profiles of specific parameters.

Selectivities of general recreational discards and shrimp bycatch could not be estimated directly, because composition data of discards were lacking. Fixed selectivities for these removals were the same as in SEDAR 28.

3.16 Indices of Abundance

The model was fit to two fishery dependent indices of relative abundance (MRIP (1986–2020) and commercial handline (1986–2020)), and one fishery independent index of age–0 recruitment (SEAMAP YOY (1989–2019)). The fishery dependent indices of abundance were limited to harvested fish. Predicted indices were conditional on selectivity of the corresponding fleet, and were computed from abundance (numbers of fish) at the midpoint of the year or, in the case of commercial handlines, biomass.

3.17 Catchability

In the BAM, catchability scales indices of relative abundance to the estimated population at large, adjusted by selectivity of the fleet or survey. For SEDAR 78, as in SEDAR 28, catchability (q) of each index was assumed to be time-invariant, and these parameters (one q per index) were estimated within BAM.

3.18 Biological Reference Points

Biological reference points (benchmarks) were calculated based on maximum sustainable yield (MSY) estimates from the Beverton–Holt spawner-recruit model with bias correction (expected values in arithmetic space). Computed benchmarks included MSY, fishing mortality rate at MSY (F_{MSY}), and spawning stock at MSY ($\mathrm{SSB}_{\mathrm{MSY}}$). In this assessment, spawning stock measures total biomass (mt) of mature females. These benchmarks are conditional on the estimated selectivity functions. The selectivity pattern used here were the selectivities at age (weighted by apical F), with effort from each fishery (including discard and bycatch mortalities) estimated as the full F averaged over the last three years of the assessment.

3.19 Fitting Criterion

Model parameters were estimated using a penalized likelihood approach in which observed removals (landings and discards) were fit closely, and observed composition data and abundance indices were fit to the degree that they were compatible. Removals and index data were fit using lognormal likelihoods. Age composition data were fit using the Dirichlet-multinomial likelihood, and only from years that met minimum sample size criteria ($nfish > 10$ and $ntrips \geq 10$.

SEDAR 28 fit composition data using the robust multinomial with iterative re-weighting (Francis 2011). Since Francis (2011), additional work on this topic has questioned the use of the multinomial distribution in stock assessment models (Francis 2014), and has recommended the Dirichlet-multinomial as an alternative (Francis 2017; Thorson et al. 2017; Fisch et al. 2021). A chief advantage of the Dirichlet-multinomial is that it is self-weighting through estimation of an additional variance inflation parameter for each composition component, making iterative re-weighting unnecessary. Another advantage is that it can better account for overdispersion, or, larger variance in the data than would be expected by the multinomial. Overdispersion can result from intra-haul correlation, which results when fish caught in the same set are more alike in length or age than fish caught in a different set (Pennington and Volstad 1994). The Dirichlet-multinomial has been implemented in Stock Synthesis (Methot and Wetzel 2013; Thorson et al. 2017) and in the BAM, and since SEDAR 41 has become the standard likelihood for fitting composition data in assessments of South Atlantic fishes.

The model includes the capability for each component of the likelihood to be weighted by user-supplied values. When applied to indices, these weights modifed the effects of the CVs derived from index standardization. CVs from index standardization are often smaller for fishery dependent indices than for fishery independent indices due to the typically larger sample sizes. Therefore, initial CVs for the fishery dependent indices were set to 0.2, similar to past SEDAR assessments, to ensure that the fishery independent index was not considered less certain than the fishery dependent index. In the base run, weights on the indices were adjusted iteratively from the initial values based on the index standardization (Table 3) until standard deviations of normalized residuals (SDNRs) were near 1.0, as recommended by Francis (2011).

For some parameters defining selectivities and Dirichlet-multinomial overdispersion parameters, normal priors were applied to maintain parameter estimates near reasonable values, and to prevent the gradient-based optimization routine from drifting into parameter space with negligible changes in the likelihood.

3.20 Configuration of a Base Run

The base run was configured as described above. This configuration does not necessarily represent reality better than all other possible configurations, and thus this assessment attempted to portray uncertainty in point estimates through sensitivity analyses and through a MCBE approach (described below).

3.21 Sensitivity Analyses

Sensitivity runs were chosen to investigate issues that arose specifically with this operational assessment. They were intended to demonstrate directionality of results with changes in inputs or simply to explore model behavior. These model runs vary from the base run as follows:

- S1: Removal of the commercial handline index
- S2: Use the Lorenzen M scaled to the low point estimate of M

- S3: Use the Lorenzen M scaled to the high point estimate of M
- S4: Steepness fixed at 0.6
- S5: Steepness fixed at 0.9
- S6: General recreational discard rate fixed at 0.1
- S7: General recreational discard rate fixed at 0.3

Retrospective analyses were also conducted by incrementally dropping one year at a time for five iterations. In these runs, the terminal years were 2019, 2018, 2017, 2016, or 2015.

3.22 Parameters Estimated

The model estimated annual fishing mortality rates of each fleet, selectivity parameters, catchability coefficients associated with indices, parameters of the mean recruitment model (R_0), annual recruitment deviations, and Dirichlet-multinomial variance inflation factors. Estimated parameters are listed in Appendix B.

3.23 Per Recruit and Equilibrium Analyses

Yield per recruit and spawning potential ratio were computed as functions of F, as were equilibrium landings, discards, and spawning biomass. Equilibrium landings and discards were also computed as functions of biomass B, which itself is a function of F. As in the computation of MSY-related benchmarks (described in §3.24), per recruit and equilibrium analyses applied the most recent selectivity patterns averaged across fleets, weighted by each fleet's F from the last three years of the assessment (2018–2020).

3.24 Benchmark/Reference Point Methods

In this assessment of Spanish mackerel, the quantities F_{MSY}, $\mathrm{SSB}_{\mathrm{MSY}}$, B_{MSY}, and MSY were estimated by the method of Shepherd (1982). In that method, the point of maximum yield is calculated from the spawner-recruit curve and parameters describing growth, natural mortality, maturity, and selectivity. The value of F_{MSY} is the F that maximizes equilibrium removals.

On average, expected recruitment is higher than that estimated directly from the spawner-recruit curve, because of lognormal deviation in recruitment. Thus, in this assessment, the method of benchmark estimation accounted for lognormal deviation by including a bias correction in equilibrium recruitment. The bias correction (ς) was computed from the variance (σ_R^2) of recruitment deviation in log space: $\varsigma = \exp(\sigma_R^2/2)$. Then, equilibrium recruitment (R_{eq}) associated with any F is,

$$R_{eq} = \frac{R_0\left[\varsigma 0.8h\Phi_F - 0.2(1-h)\right]}{(h-0.2)\Phi_F} \tag{1}$$

where R_0 is virgin recruitment, h is steepness, and $\Phi_F = \phi_F/\phi_0$ is spawning potential ratio given growth, maturity, and total mortality at age (including natural and fishing mortality rates). The R_{eq} and mortality schedule imply an equilibrium age structure and an average sustainable yield (ASY). The estimate of F_{MSY} is the F giving the highest ASY, and the estimate of MSY is that ASY. The estimate of $\mathrm{SSB}_{\mathrm{MSY}}$ follows from the corresponding equilibrium age structure, as does the benchmark estimate of discard mortalities (D_{MSY}), here separated from ASY (and consequently, MSY).

Estimates of MSY and related benchmarks are conditional on selectivity pattern. The selectivity pattern used here was an average of terminal-year selectivities from each fleet, where each fleet-specific selectivity was weighted in proportion to its corresponding estimate of F averaged over the last three years (2018–2020). If the selectivities or relative fishing mortalities among fleets were to change, so would the estimates of MSY and related benchmarks.

For this stock, the maximum fishing mortality threshold (MFMT) is defined by the SAFMC as F_{MSY}, and the minimum stock size threshold (MSST) as $75\%\mathrm{SSB}_{\mathrm{MSY}}$. Overfishing is defined as $F >$ MFMT and overfished as SSB $<$ MSST. Current status of the stock is represented by SSB in the latest assessment year (2020), and current status of the fishery is represented by the geometric mean of F from the latest three years (2018–2020).

3.25 Uncertainty and Measures of Precision

As in SEDAR 28, this assessment used a MCBE approach to characterize uncertainty in results of the base run. Monte Carlo and bootstrap methods (Efron and Tibshirani 1993; Manly 1997) are often used to characterize uncertainty in ecological studies, and the mixed approach has been applied successfully in stock assessment, including Restrepo et al. (1992), Legault et al. (2001), SEDAR4 (2004), and many South Atlantic SEDAR assessments since SEDAR19 (2009). The approach is among those recommended for use in SEDAR assessments (SEDAR Procedural Guidance 2010), and it is considered to be one of the more complete characterizations of uncertainty used in stock assessments across the United States.

The approach translates uncertainty in model input into uncertainty in model output, by fitting the model many times with different values of "observed" data and key input parameters. A main advantage of the approach is that the results describe a range of possible outcomes, so that the ensemble of models characterizes uncertainty in results more thoroughly than any single fit or handful of sensitivity runs (Scott et al. 2016; Jardim et al. 2021). A minor disadvantage of the approach is that computational demands are relatively high, but this can largely be mitigated through use of parallel processing.

In this assessment, the BAM was successively re-fit in $n = 4000$ trials that differed from the original inputs by bootstrapping on data sources, and by Monte Carlo sampling of several key input parameters. The value of $n = 4000$ was chosen because a minimum of 3000 runs were desired, and it was anticipated that not all runs would converge or otherwise be valid. Of the 4000 trials, approximately 1% were discarded, because the model did not properly converge (the Hessian was not positive definite or a parameter hit a bound). This left $n = 3957$ MCBE runs to characterize uncertainty, which was sufficient for convergence of standard errors in management quantities. All runs were given equal weight when forming the ensemble of results (Jardim et al. 2021).

The MCBE analysis should be interpreted as providing an approximation to the uncertainty associated with each output. The results are approximate for two related reasons. First, not all combinations of Monte Carlo parameter inputs are equally likely, as biological parameters might be correlated. Second, all runs are given equal weight in the results, yet some might provide better fits to data than others.

3.26 Bootstrap of Observed Data

To include uncertainty in time series of observed landings, discards, and indices of abundance, multiplicative lognormal errors were applied through a parametric bootstrap. To implement this approach in the MCB trials, random variables ($x_{s,y}$) were drawn for each year y of time series s from a normal distribution with mean 0 and variance $\sigma^2_{s,y}$ [that is, $x_{s,y} \sim N(0, \sigma^2_{s,y})$]. Annual observations were then perturbed from their original values ($\hat{O}_{s,y}$),

$$O_{s,y} = \hat{O}_{s,y}[\exp(x_{s,y} - \sigma^2_{s,y}/2)] \tag{2}$$

The term $\sigma_{s,y}^2/2$ is a bias correction that centers the multiplicative error on the value of 1.0. Standard deviations in log space were computed from CVs in arithmetic space, $\sigma_{s,y} = \sqrt{\log(1.0 + CV_{s,y}^2)}$. As used for fitting the base run, CVs of landings and discards were assumed to be 0.05, and CVs of indices of abundance were those provided by, or modified from, the DW (tabulated in §2 of this assessment report).

Uncertainty in age compositions were included by drawing new distributions for each year of each data source, following a multinomial sampling process. Ages of individual fish were drawn at random with replacement using the cell probabilities of the original data. For each year of each data source, the number of individuals sampled was the same as in the original data (number of fish).

3.27 Monte Carlo Sampling

In each successive fit of the model, several parameters were fixed (i.e., not estimated) at values drawn at random from distributions. The steepness, natural mortality, and general recreational discard mortality distributions are described below.

3.28 Steepness

As in SEDAR 28, steepness could not be estimated with stability in the model. Steepness values above 0.60 appeared to be equally likely in the likelihood profile. Steepness was fixed at 0.75 for the base run and uncertainty in the parameters was characterized by a truncated normal distribution with 0.6 and 0.9 as the lower and upper bounds respectively.

3.29 Natural Mortality

As in each model run, the vector of age-specific natural mortality (Lorenzen estimator) was scaled to the fish–only Hoenig (1983) age-invariant M as was done for the base run. The point estimate of natural mortality ($M = 0.35$) was based on a maximum age of 12. To estimate uncertainty, a new M value was drawn for each MCB trial from a truncated normal distribution of (range [0.30, 0.42]) with mean equal to the point estimate ($M = 0.35$) and standard deviation set to provide 95% confidence limits at the bounds. The range was reduced from SEDAR 28 and corresponds to maximum age $+/-2$ instead of the range of point estimates across many different methods to calculate M (range [0.16, 0.54]). Each realized value of M was used to scale the age-specific Lorenzen M, as in the base run.

3.30 General Recreational Discard Mortality

As in SEDAR 28, discard mortalities δ were subjected to Monte Carlo variation as follows. A new value for general recreational discard mortality was drawn for each MCB trial from a truncated normal distribution range [0.10, 0.30] with mean equal to the point estimate ($\delta = 0.20$) and standard deviation set to provide 95% confidence limits at the bounds.

3.31 Projection Methods

Projections were run to predict stock status in years after the assessment, 2021–2025.

The structure of the projection model was the same as that of the assessment model, and parameter estimates were those from the assessment. A single selectivity curve was applied to calculate landings computed by averaging selectivities across fleets using geometric mean Fs from the last three years of the assessment period, similar to computation of MSY benchmarks (§3.24).

3.31.1 Initialization of Projections

Although the terminal year of the assessment is 2020, the assessment model computes abundance at age (N_a) at the start of 2021. For projections, those estimates were used to initialize N_a. However, the assessment has no information to inform the strength of 2021 recruitment, and thus it computes 2021 recruits (N_1) as the expected value, that is, without deviation from the estimate of mean recruitment, and corrected to be unbiased in arithmetic space. In the stochastic projections, lognormal stochasticity was applied to these abundances after adjusting them to be unbiased in log space, with variability based on the estimate of σ_R. Thus, the initial abundance in year one (2021) of projections included this variability in N_1. The deterministic projections were not adjusted in this manner, because deterministic recruitment follows mean recruitment.

Fishing rates that define the projections were assumed to start in 2023. Because the assessment period ended in 2020, the projections required an initialization period (2021 and 2022). L_{current} (the average landings over the last 3 years in the assessment model) was assumed during the interim period.

3.31.2 Uncertainty of Projections

To characterize uncertainty in future stock dynamics, stochasticity was included in replicate projections, each an extension of a single assessment fit from the ensemble. Thus, projections carried forward uncertainties in natural mortality and discard mortality, as well as in estimated quantities such as spawner-recruit parameters (R_0 and σ_R, selectivity curves, and in initial (start of 2021) abundance at age.

Initial and subsequent recruitment values were generated with stochasticity using a Monte Carlo procedure, in which the estimated recruitment of each model within the ensemble is used to compute mean annual recruitment values ($\bar{R}_y$). Variability is added to the mean values by choosing multiplicative deviations at random from a lognormal distribution,

$$R_y = \bar{R}_y \exp(\epsilon_y). \tag{3}$$

Here ϵ_y is drawn from a normal distribution with mean 0 and standard deviation σ_R, where σ_R is the standard deviation from the relevant ensemble model component.

The procedure generated 20,000 replicate projections of models within the ensemble drawn at random (with replacement). In cases where the same model run was drawn, projections would still differ as a result of stochasticity in projected recruitment streams. Central tendencies were represented by the deterministic projections of the base run, as well as by medians of the stochastic projections. Precision of projections was represented graphically by the 5^{th} and 95^{th} percentiles of the replicate projections.

3.31.3 Projection Scenarios

The ToRs for this assessment did not define projections scenarios. The SEDAR 78 panel defined three scenarios: F_{current}, F_{MSY}, and $75\%F_{\text{MSY}}$. In each, the landings in the interim period (2021–2022) were calculated based on F_{current}.

- Scenario 1: $F = F_{\text{current}}$, with L_{current} also assumed for the interim period.
- Scenario 2: $F = F_{\text{MSY}}$, with L_{current} assumed for the interim period.
- Scenario 3: $F = 75\%F_{\text{MSY}}$, with L_{current} assumed for the interim period.

4 Stock Assessment Results

4.1 Measures of Overall Model Fit

In general, the BAM fit well to the available data. Predicted age compositions were reasonably close to observed data in most years (Figures 2 and 3). The model was configured to fit observed commercial and general recreational removals closely (Figures 4–10). Fits to indices of abundance were reasonable, though the commercial handline index was generally underfit between 2004 and 2020 (Figures 11–13). There was no clear explanation for this trend and a sensitivity run to evaluate the exclusion of the commercial handline index is discussed in 4.11. The SEAMAP YOY index suggests highly variable recruitment from year to year; however, mismatches between trawl surveys and the timing of migration are an alternative explanation for the variability.

4.2 Parameter Estimates

Estimates of all parameters from the catch-age model are shown in Appendix B. Estimates of management quantities and some key parameters are reported in sections below.

4.3 Stock Abundance and Recruitment

Estimated abundance at age shows a similar pattern across all years with most variation in youngest ages (Figure 14). Annual number of recruits is shown in Table 9 (age-0 column) and in Figure 15.

4.4 Total and Spawning Biomass

Estimated biomass at age follows a similar pattern as did abundance (Table 10 and Figure 16). Total biomass and spawning biomass show nearly identical trends with near–decadal fluctuation in overall landings. The relative contribution and annual variability of YOY fish is lower in the biomass at age due to non-linear size at age.

4.5 Fishery Selectivity

Selectivities of landings from commercial and general recreational fleets are shown in Figures 17, 18, 19, 20, and 21. Selectivities of discards from commercial and general recreational fleets are shown in Figures 22 and 23. Selectivities are tabulated in Table 12. Estimated selectivities of removals indicate that full selection occurs by age one for commercial pound net and general recreational fleets and age three for commercial handline, cast net, and gillnet fleets. General recreational discards and shrimp bycatch were assumed to be mostly YOY (Figures 23 and 23).

Average selectivities of landings, dead discards, and the total weighted average of all selectivities were computed from F-weighted selectivities in the most recent three assessment years (Figure 24, Table 12). These average selectivities were used in computation of point estimates of benchmarks, as well as in projections.

4.6 Fishing Mortality

Estimates of total F by fleet are shown in Figure 25 and Table 13, and estimates of F at age are shown in Table 14. In any given year, the maximum F at age (i.e., apical F) may be less than that year's sum of fully selected Fs across fleets. This inequality is due to the combination of two features of estimated selectivities: full selection occurs at different ages among gears and several sources of mortality have dome-shaped selectivity.

Alternative measures of fishing intensity have implications similar to those of apical F (Figure 26). The value of SPR_F has remained near or above the equilibrium MSY level with the exception of the terminal year which was dominated by removals from the general recreational fleet.

Throughout most of the assessment period, estimated landings and discard mortalities in number of fish have been split evenly between commercial and general recreational sectors (Figures 27 and 28). Early commercial landings were dominated by gillnet removals but shifted to a mix of cast net, gillnet, and handline starting in about 2004. Table 18 shows total landings at age in numbers, and Table 19 in 1000 lb. Table 20 shows total dead discards at age in thousand pounds, and Table 21 in weight.

4.7 Stock-Recruitment Parameters

The estimated Beverton–Holt spawner-recruit curve is shown in Figure 31. Variability about the curve was estimated only at relatively low levels of spawning biomass, because composition data required for estimating recruitment deviations became available only after spawning stock had been diminished. The effect of density dependence on recruitment can be examined graphically via the estimated recruits per spawner as a function of spawners (Figure 31).

The mean recruit relationship and variability around that mean are shown in Figure 31. Values of recruitment–related parameters were as follows: unfished YOY recruitment $\widehat{R_0} = 21939130$, and standard deviation of recruitment residuals in log space was fixed at $\sigma_R = 0.6$ (which resulted in bias correction of $\varsigma = 1.20$). Uncertainty in these quantities was estimated through the MCBE analysis (Figure 32).

4.8 Per Recruit and Equilibrium Analyses

Yield per recruit and spawning potential ratio were computed as functions of F. These computations applied the most recent selectivity patterns averaged across fleets, weighted by F from the last three years (2018–2020) (Figure 33).

As in per recruit analyses, equilibrium spawning biomass was computed as a function of F (Figure 34). Similarly, equilibrium biomass and removals are functions of F, allowing for their relationships to be depicted together (Figure 35).

4.9 Benchmarks / Reference Point

As described in §3.24, biological reference points (benchmarks) were derived analytically assuming equilibrium dynamics, corresponding to the estimated spawner-recruit curve with bias correction (Figure 31). This approach is consistent with methods used in rebuilding projections (i.e., fishing at F_{MSY} yields MSY from a stock size of $\mathrm{SSB}_{\mathrm{MSY}}$). $F_{\mathrm{OY}} = 75\%F_{\mathrm{MSY}}$ was considered as another possible values of F at optimum yield (OY). Standard errors of benchmarks were approximated as those from ensemble modeling §3.25.

Maximum likelihood estimates (base run) of benchmarks, as well as median values from MCBE analysis, are summarized in Table 22. Point estimates of MSY-related quantities were $F_{\mathrm{MSY}} = 0.52$ (y^{-1}), MSY = 8210.19 (1000 lb), $B_{\mathrm{MSY}} = 19588.3$ (mt), and $\mathrm{SSB}_{\mathrm{MSY}} = 6405.87$ (mature female biomass, mt). Median estimates were $F_{\mathrm{MSY}} = 0.52$ (y^{-1}), MSY = 8351.35 (1000 lb), $B_{\mathrm{MSY}} = 19820.72$ (mt), and $\mathrm{SSB}_{\mathrm{MSY}} = 6410.25$ (mature female biomass, mt). Distributions of these benchmarks from the MCBE analysis are shown in Figure 36.

4.10 Status of the Stock and Fishery

Estimated time series of stock status SSB/MSST showed a near–decadal fluctuation above MSST (Figure 37, Table 11). Base-run estimates of spawning biomass have remained above $\mathrm{SSB}_{\mathrm{MSY}}$. Current stock status was estimated in the base run to be $\mathrm{SSB}_{2020}/\mathrm{MSST} = 1.4$ and $\mathrm{SSB}_{2020}/\mathrm{SSB}_{\mathrm{MSY}} = 1.05$ (Table 22), indicating that the stock is not overfished. Median values from the MCBE analysis indicated similar results SSB/MSST= 1.42 and $\mathrm{SSB}/\mathrm{SSB}_{\mathrm{MSY}}$= 1.07 (Figure 37). The uncertainty analysis suggested that the terminal estimate of stock status is robust (Figures 38 and 40). Of the MCBE runs, 92.6% indicated that the stock was above MSST in 2020.

The estimated time series of F/F_{MSY} suggests that overfishing has not occurred throughout most of the assessment period except for 2020 (Table 11, Figure 37). Current fishery status in the terminal year, with current F represented by the geometric mean from years 2018–2020, was estimated by the base run to be $F/F_{\mathrm{MSY}} = 0.77$ (Table 22). The fishery status was also robust (Figures 38 - 40). Of the MCBE runs, approximately 90% agreed with the base run that the stock is not currently experiencing overfishing.

Compared to SEDAR 28, the qualitative results of stock and fishery status are similar (Figure 41).

4.11 Sensitivities and Retrospective Runs

Sensitivity runs, described in §3.21, were used for exploring data or model issues that arose during the assessment process, for evaluating implications of assumptions in the base assessment model, and for interpreting MCBE results in terms of expected effects of input parameters. In some cases, sensitivity runs are simply a tool for better understanding model behavior, and therefore all runs are not considered equally plausible in the sense of alternative states of nature. Time series of F/F_{MSY} and $\mathrm{SSB}/\mathrm{SSB}_{\mathrm{MSY}}$ are plotted to demonstrate sensitivity to the changing conditions in each run. This operational assessment explored sensitivity of the base run to changes in data input, natural mortality, steepness, and general recreational discard mortality (Figures 42–45). Of these modifications, results were most sensitive to the scale of natural mortality and steepness.

Retrospective analyses suggest no concerning patterns of estimating F or SSB in the terminal year (Figure 46) or status indicators (Figure 47). Terminal-year recruitment was variable across retrospective peels.

4.12 Projections

Since the stock status is not overfished or undergoing overfishing, three projections are provided for completeness and were recommended by the SEDAR 78 panel.

Projection scenario 1, which assumed L_{current}(average landings over the last 3 years) during the interim period (2021-2022) and $F = F_{\text{current}}$ for following years, predicted the stock to decrease until management measure take place and then increase back to SSB_{MSY} (Figure 48, Table 24).

Projection scenario 2, which assumed L_{current}(average landings over the last 3 years) during the interim period (2021-2022) and $F = Fmsy$ for following years, predicted the stock to decrease until management measure take place and then increase but not recover to SSB_{MSY} in the terminal year (Figure 49, Table 25).

Projection scenario 3, which assumed L_{current}(average landings over the last 3 years) during the interim period (2021-2022) and $F = 75\%Fmsy$, predicted the stock to decrease until management measure take place and then increase back to SSB_{MSY} (Figure 50, Table 26).

4.13 Discussion

The base run of the BAM indicated that the stock is not overfished SSB/MSST =1.4, and that overfishing is not occuring based on the 3–year geometric mean F/F_{MSY} =0.77. The 2020 point estimate for F/F_{MSY} indicated overfishing primarily due to a large increase in the general recreational landings during the COVID-19 pandemic. Should this high rate of fishing continue after 2020, overfishing would likely ensure. Indeed, preliminary MRIP estimates of Spanish mackerel landings in 2021 were higher than in 2020. The stock continues to show resilience to fishing effort as in SEDAR 28 (Figure 41). Neither of these models show a stock that was overfished or near overfishing in 2007 as SEDAR17 (2008) indicated.

The Monte Carlo/bootstrap ensemble analyses showed widespread agreement with the qualitative results of the base run. Of all MCBE runs, 92.6% showed that the stock is not overfished, and 90.0% showed that overfishing is not occurring.

4.13.1 Comments on the Assessment

In addition to including the more recent years of data, this operational assessment contained several modifications to the previous data of SEDAR 28, such as the use of modern MRIP methodology, the use of the Dirichlet–multinomial distribution to fit age compositions, pooling age compositions across years for fleets with low annual sample sizes, modification to selectivity functions applied to landings, update of the growth models and natural mortality, removing sex–specific growth and selectivity, and changing the start year of the model. The assessment model itself was also modernized to the current version of BAM. The sum of these improvements should result in a more robust assessment.

There is a lack of available fishery independent indices of abundance for this species. The schooling behavior of Spanish mackerel makes a random survey of their population particularly difficult. The one fishery independent index used (SEAMAP YOY) was highly variable, as would be expected for a recruitment index.

In general, fishery dependent indices of abundance may not track actual abundance well, because of factors such as hyperdepletion or hyperstability. Furthermore, this issue can be exacerbated by management measures. In this assessment, the commercial handline index was generated from Florida trip ticket data. There was a shift in the commercial handline index in 2004 after which a run of positive residuals persisted in the model fit. A sensitivity run excluding the commercial handline index did not influence the results in the terminal year of the assessment. The

index was included in the model but should be investigated further in future assessments. In general, management measures in the southeast U.S. have made the continued utility of fishery dependent indices questionable. This situation amplifies the importance of fishery independent sampling.

Natural mortality plays a driving role in this assessment, as it does in most. The pattern of natural mortality at age affects multiple outputs, including annual fishing rates, benchmarks, and equilibrium age structure expected at MSY. The model could estimate steepness at 0.73 but it was only weakly informed above 0.60 and would stay close to the starting value. As in SEDAR 28, steepness was fixed at 0.75 as a mid-point of the range over which no likelihood signal was available.

4.14 Comments on the Projections

As usual, projections should be interpreted in light of the model assumptions and key aspects of the data. Some major considerations are the following:

- In general, projections of fish stocks are highly uncertain, particularly in the long term (e.g., beyond 5–10 years).
- Although projections included many major sources of uncertainty, they did not include structural (model) uncertainty. That is, projection results are conditional on one set of functional forms used to describe population dynamics, selectivity, recruitment, etc.
- Fisheries were assumed to continue fishing at their estimated current proportions of total effort, using the estimated current selectivity patterns. New management regulations that alter those proportions or selectivities would likely affect projection results.
- The projections assumed that the estimated spawner-recruit relationship applies in the future and that past residuals represent future uncertainty in recruitment. If future recruitment is characterized by runs of large or small year classes, possibly due to environmental or ecological conditions, stock trajectories may be affected.

4.15 Research Recommendations

The research recommendations from the SEDAR 78 panel were as follows:

- Development of a fishery-independent survey for pelagic species would decrease reliance on a fishery-dependent index of abundance that has unexplained trends in residual values in recent years.
- Examine how schooling or migratory dynamics may influence the catchability of the species. In particular, research the assumption of the hyperstability of indices that sample the schooling portion of the stock.
- Age-dependent natural mortality was estimated by indirect methods (Lorenzen) for this assessment. Telemetry- and conventional-tagging programs can provide alternative estimates of natural mortality. Investigate new methods for determining point estimates for natural mortality.

4.16 Sampling Recommendations

- Limited information is available for shrimp bycatch in the Atlantic. Comprehensive observer coverage across space and time are needed to adequately capture the scale and size distribution of bycatch for Spanish mackerel and other species.
- The general recreational discards have increased dramatically in the last 2 years of this assessment. A better understanding of the size composition and mortality of discarded fish would improve the assessment, especially if discards continue to increase due to effort or future management changes.
- Implement systematic age sampling for the general recreational and commercial sectors. Age samples were important for this assessment for determining key parameters but sample sizes were limited, particularly for the general recreational sector, commercial handline and commercial cast net sectors, which account for the majority of the recent landings.

Table 2. Observed time series of landings (L) and discards (D) for commercial handline (cH), commercial gill net (cG), commercial pound net(cP), commercial cast net(cC), shrimp bycatch (SB), and general recreational (GR) fisheries. Commercial landings are in units of 1000 lb whole weight; all others are in units of 1000 fish. Discards include all released fish, live or dead.

Year	L.cH	L.cG	L.cP	L.cC	L.GR	D.SB	D.GR

Table 11. Estimated time series and status indicators. Fishing mortality rate is full F, which includes discard mortalities. Total biomass (B, mt) is at the start of the year, and spawning biomass (SSB, mt) at the end of July (time of peak spawning). The MSST *is defined by* $\text{MSST} = 75\%\text{SSB}_{\text{MSY}}$. *SPR is static spawning potential ratio.*

Table 13. Estimated time series of fully selected fishing mortality rates for commercial handline (F.cH), commercial pound net (F.cP), commercial gill net (F.cG), commercial cast net (F.cC), general recreational (F.GR), general recreational discards(F.GR.D), and shrimp bycatch (F.SB.D). Also shown is apical F (Full.F), the maximum F at age summed across fleets. Full F may not equal the sum of fully selected F's because of dome-shaped selectivities.

Year	F.cH	F.cP	F.cG	F.cC	F.GR	F.GR.D	F.SB.D	Full.F

Table 22. Estimated status indicators, benchmarks, and related quantities from the base run of the Beaufort catch-age model, conditional on estimated current selectivities averaged across fleets. Also presented are median values and measures of precision (standard errors, SE) from the Monte Carlo/Bootstrap ensemble (MCBE) analysis. Rate estimates (F) are in units of y^{-1}; status indicators are dimensionless; and biomass estimates are in units of metric tons or pounds, as indicated. Spawning stock biomass (SSB) is measured as total mature female biomass. The definitions of MSST in this assessment is $MSST = 75\%SSBMSY$.

Quantity	Units	Estimate	Median	SE
F_{MSY}	y^{-1}	0.516	0.523	0.111
$75\%F_{\text{MSY}}$	y^{-1}	0.387	0.392	0.083
$F_{30\%}$	y^{-1}	0.608	0.615	0.059
$F_{40\%}$	y^{-1}	0.410	0.414	0.038
B_{MSY}	metric tons	19588	19821	2232
SSB_{MSY}	metric tons	6406	6410	1122
MSST	metric tons	4804	4808	842
MSY	1000 lb whole	8210	8351	411
R_{MSY}	thousands	22792	23392	3015
$L_{85\%}Fmsy$	1000 lb whole	8149	8287	410
$L_{75\%}Fmsy$	1000 lb whole	8024	8158	408
$L_{65\%}Fmsy$	1000 lb whole	7807	7932	407
$F[2018-2020]$	y^{-1}	0.40	0.39	0.05
$F_{2018-2020}/F_{\text{MSY}}$	—	0.77	0.74	0.21
SSB_{2020}/MSST	—	1.40	1.42	0.34
$\text{SSB}_{2020}/\text{SSB}_{\text{MSY}}$	—	1.05	1.07	0.25

Table 23. Results from sensitivity runs of the Beaufort Assessment Model. Current F represented by geometric mean of last three assessment years. Spawning stock was based on total (population) fecundity of mature females. Runs should not all be considered equally plausible.

Run	Description	F_{MSY}	SSB_{MSY} (mt)	B_{MSY} (mt)	MSY (1000 lb)	$F_{2018--2020}/F_{MSY}$	SSB/SSB_{MSY}	$SSB_{2020}/MSST$	R0 (1000)

4.19 Figures

Figure 1. Mean length at age (mm) of the population (purple, solid), females (green, dashed) and the fished population (yellow, dotted).

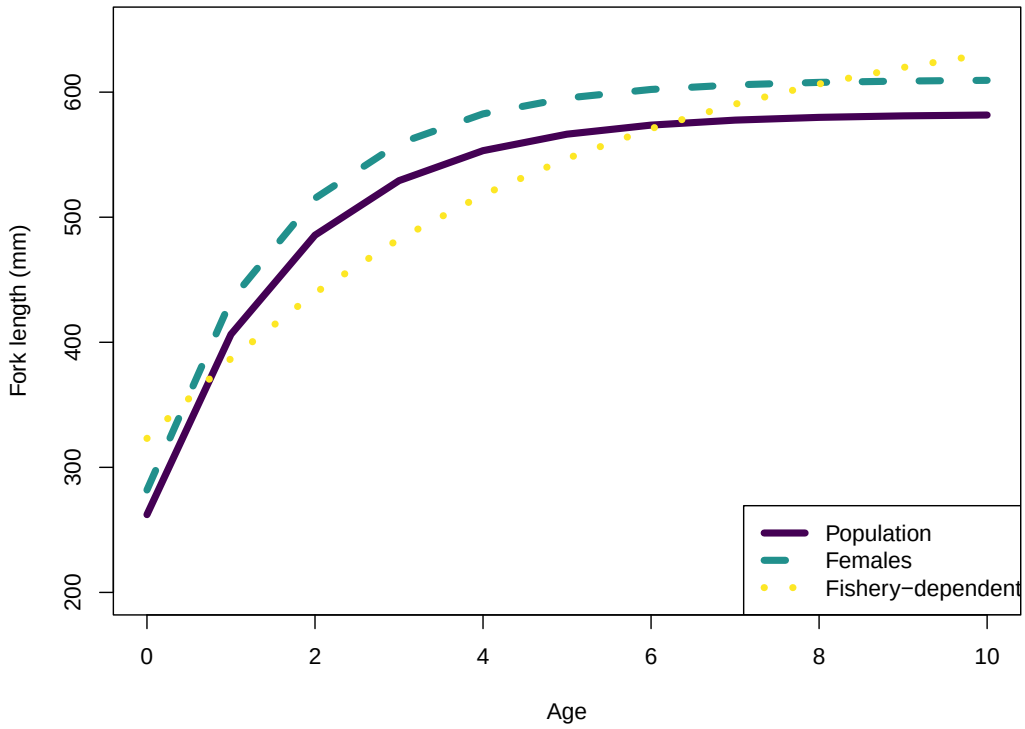

Figure 2. Observed (open circles) and estimated (solid line) annual age compositions by fleet. In panel definition of series; acomp refers to age compositions, cH to commercial handline, cP to pound nets, cG to gill nets, cC to cast nets, and GR to recreationl.

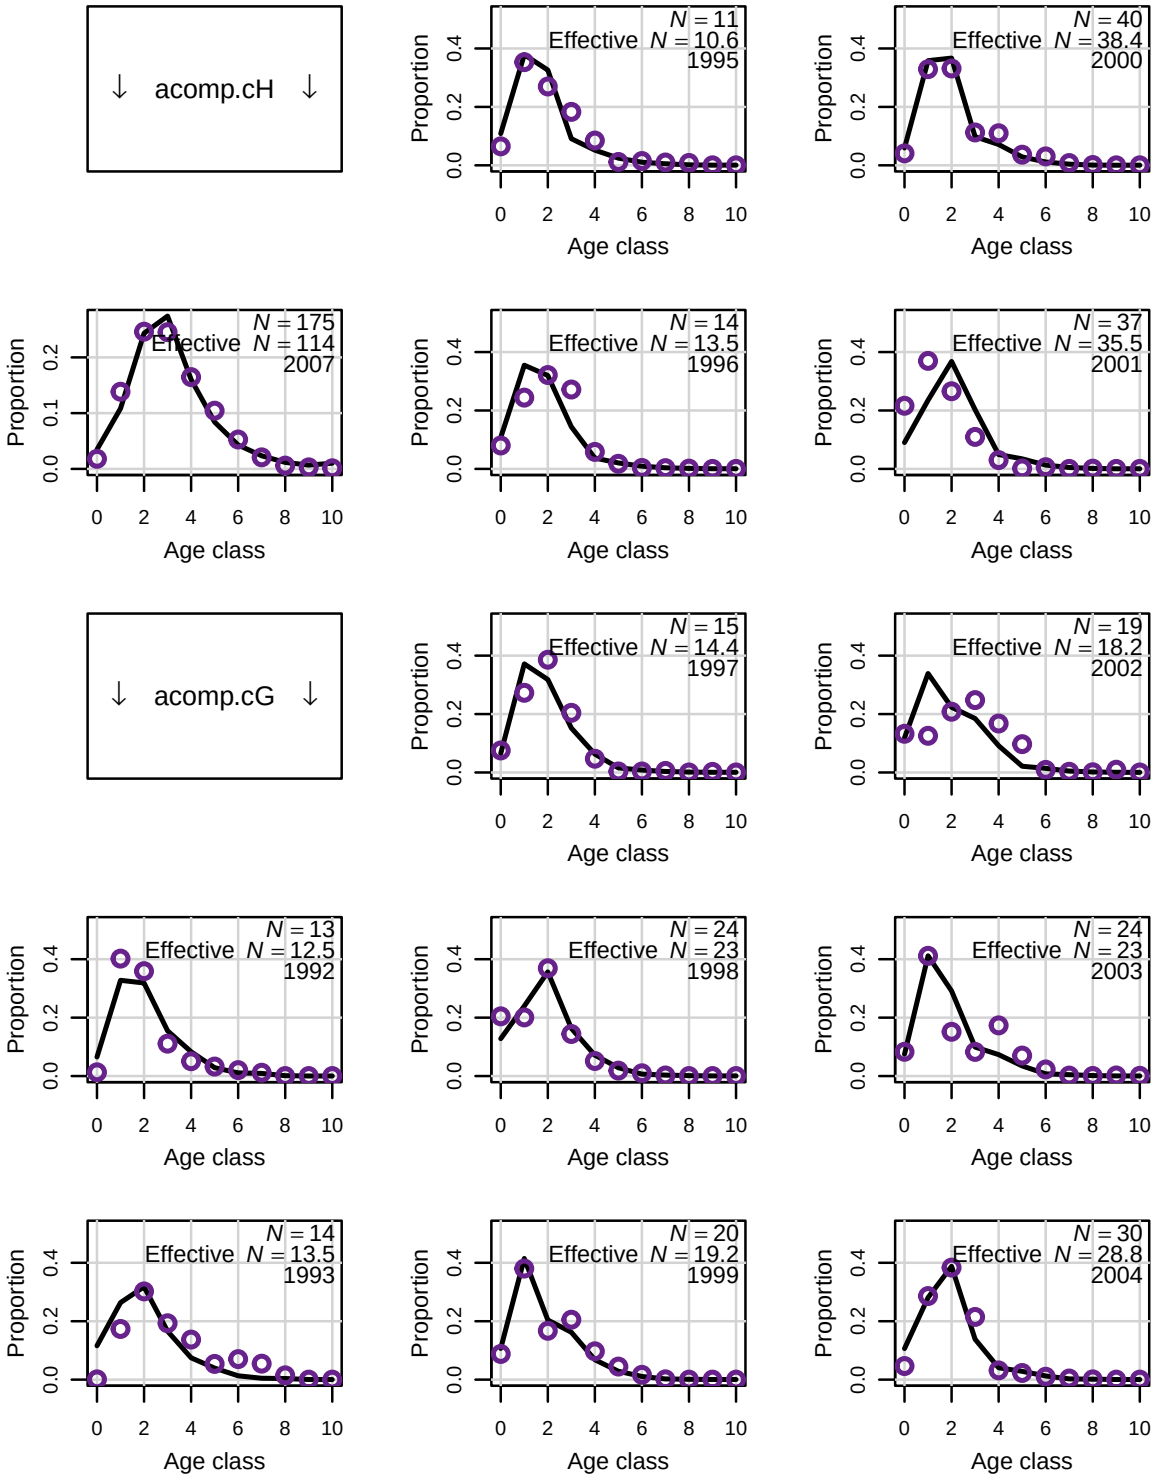

Figure 2. (cont.) Observed (open circles) and estimated (solid line) annual age compositions by fleet.

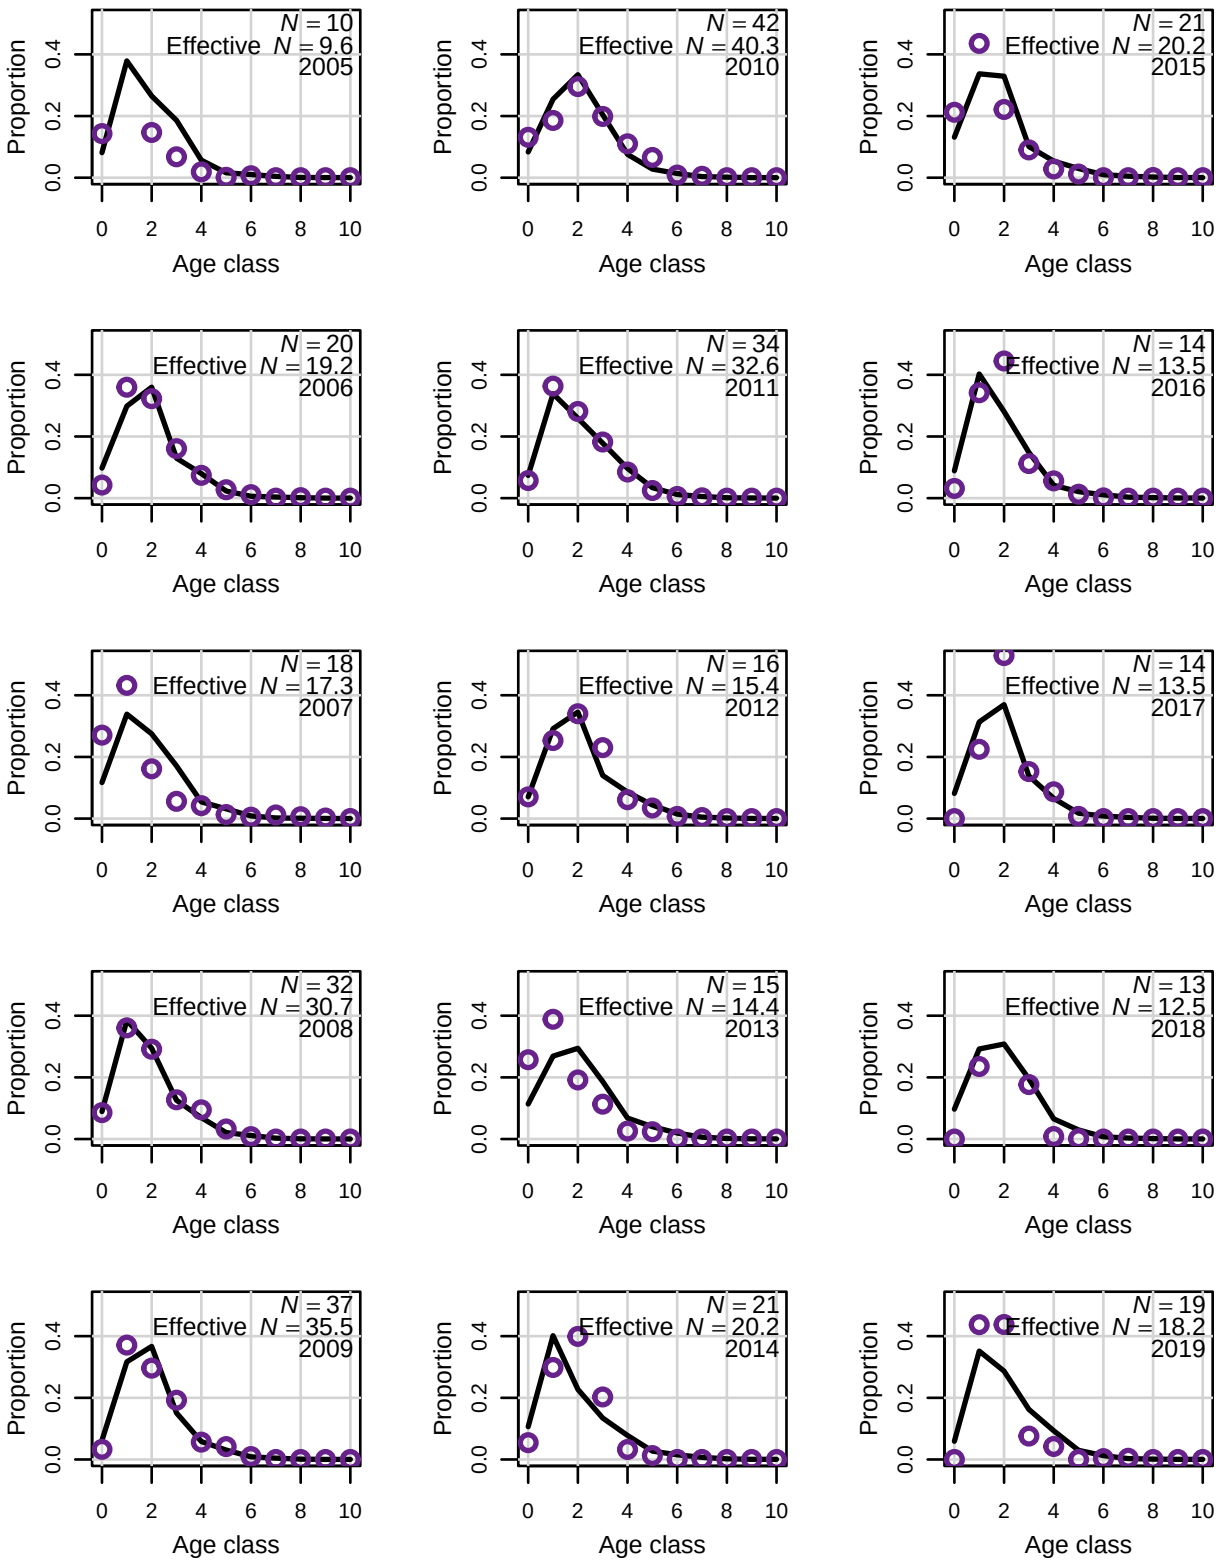

Figure 2. (cont.) Observed (open circles) and estimated (solid line) annual age compositions by fleet.

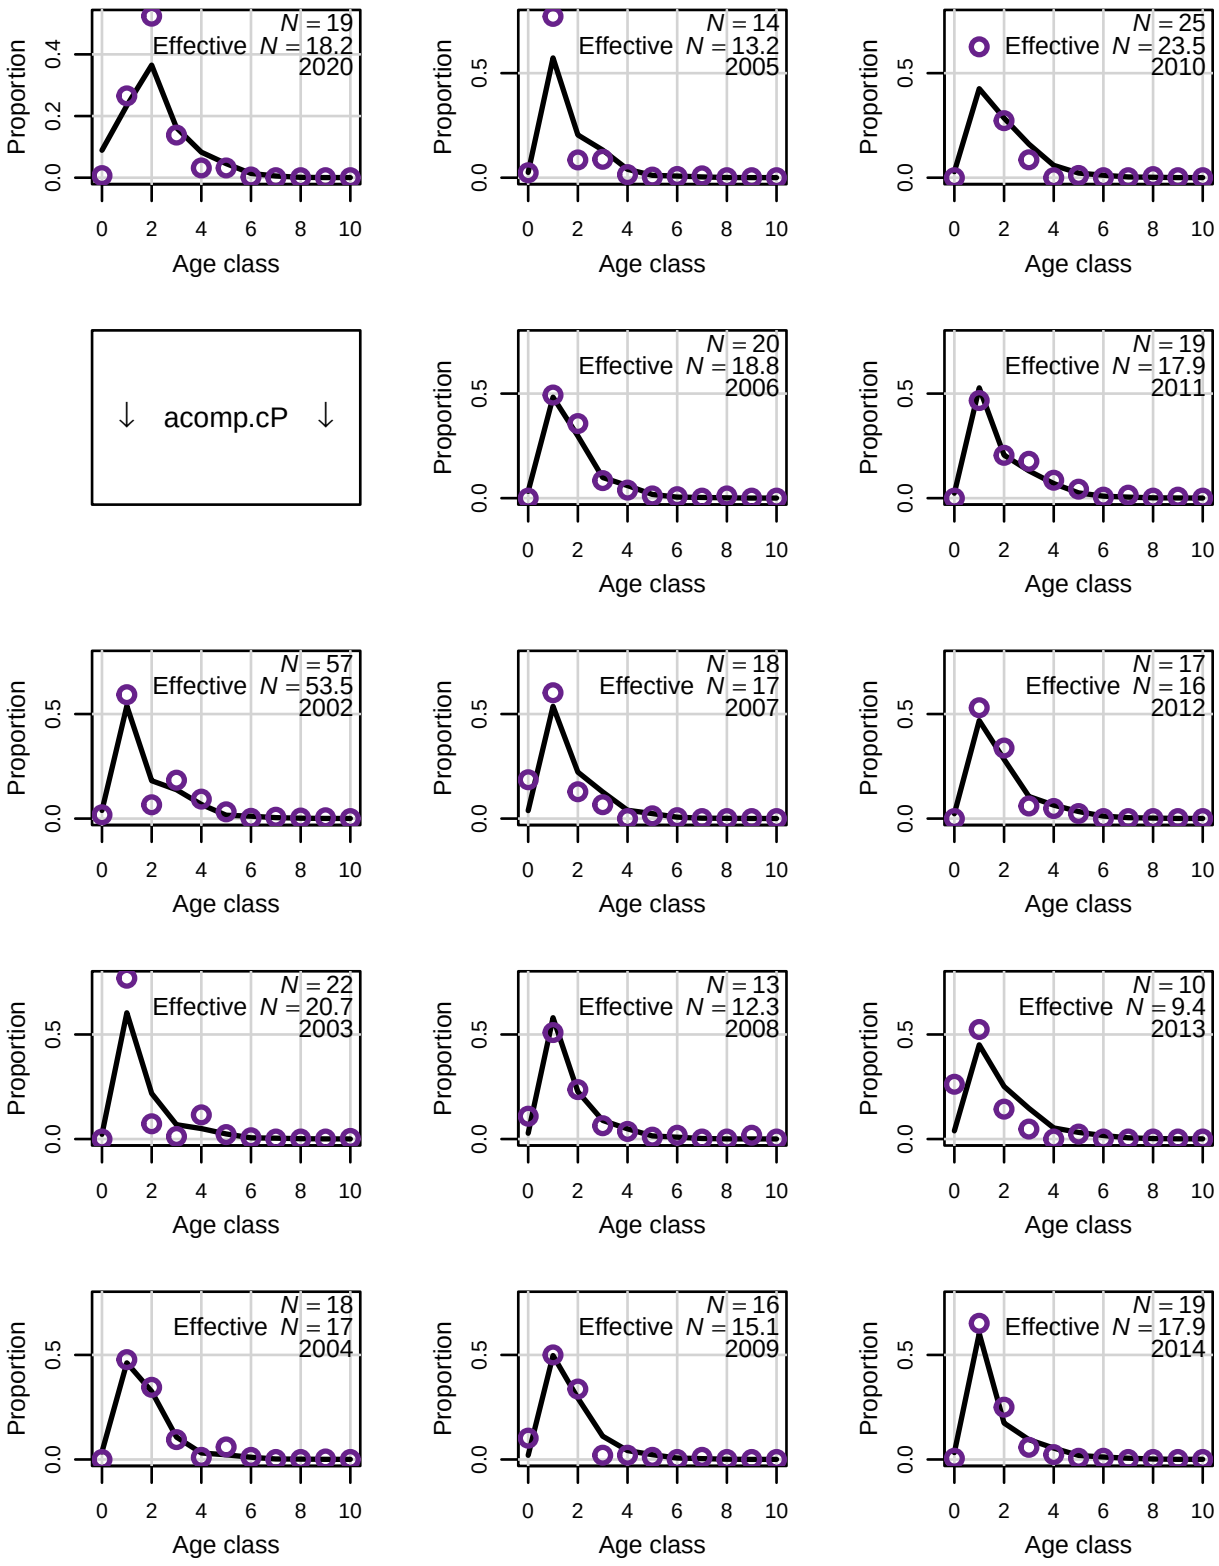

Figure 2. (cont.) Observed (open circles) and estimated (solid line) annual age compositions by fleet.

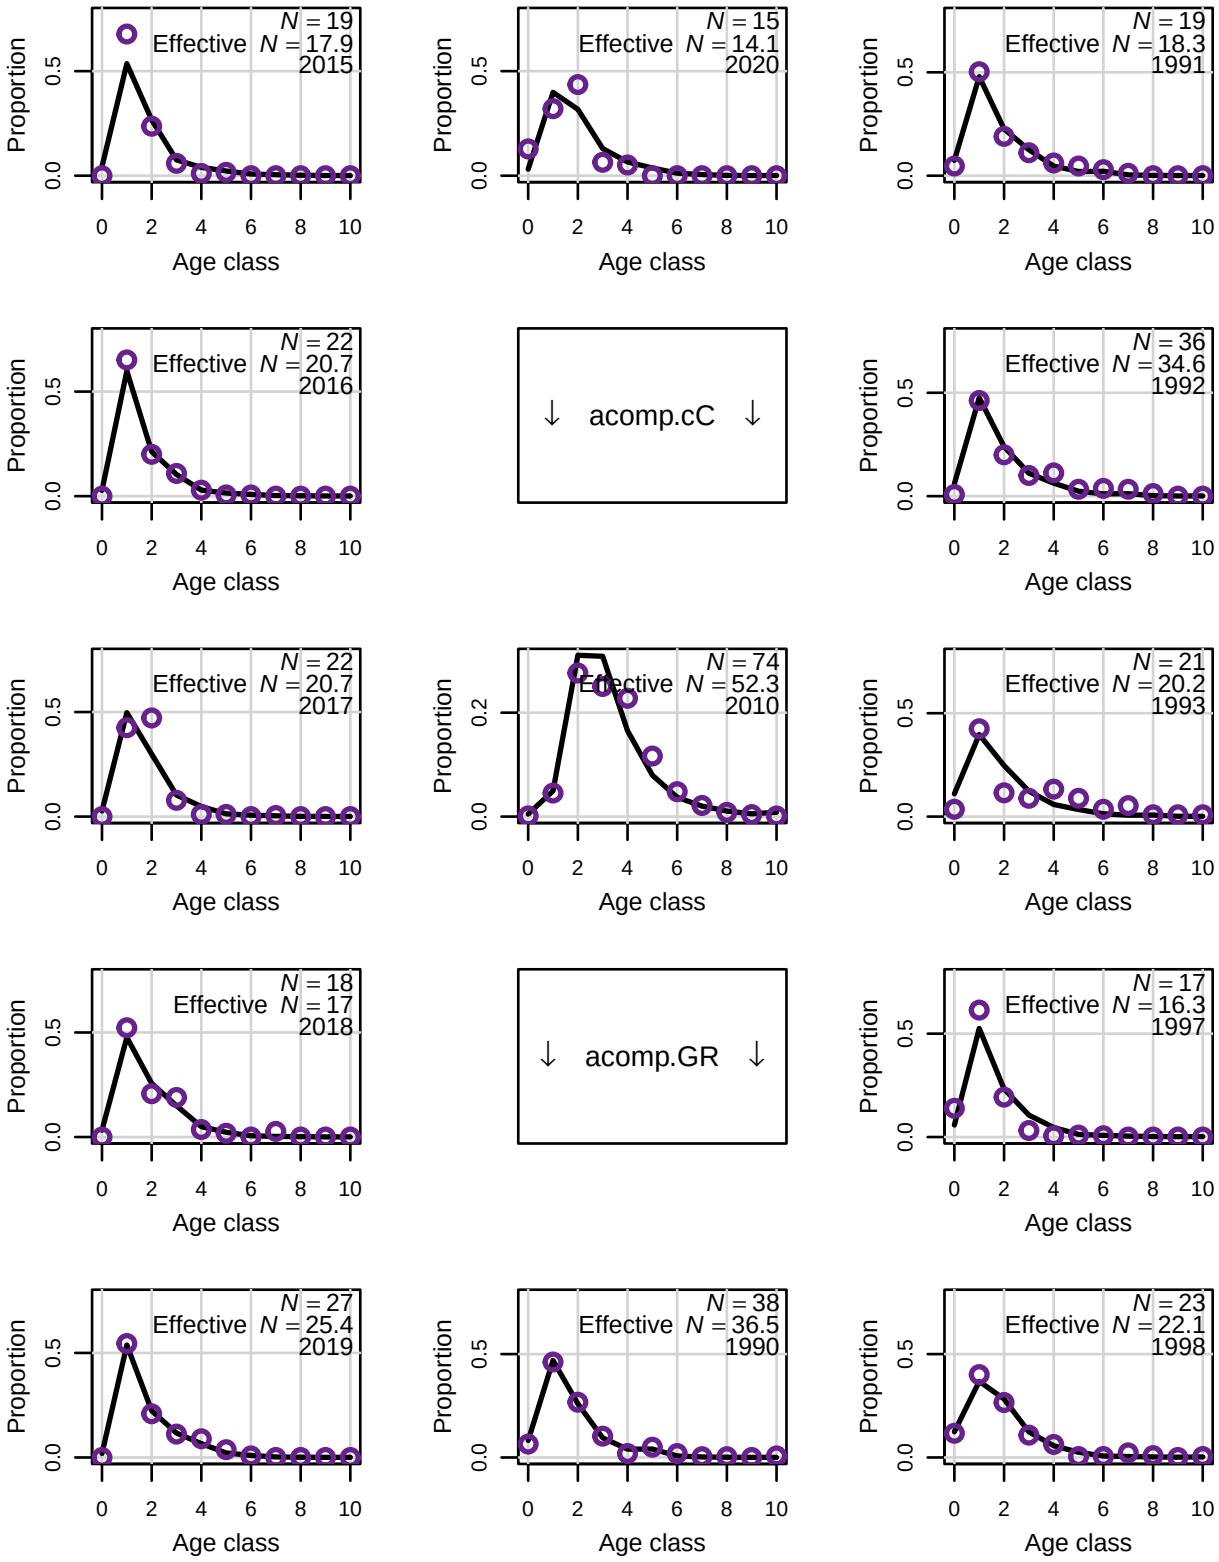

Figure 2. (cont.) Observed (open circles) and estimated (solid line) annual age compositions by fleet.

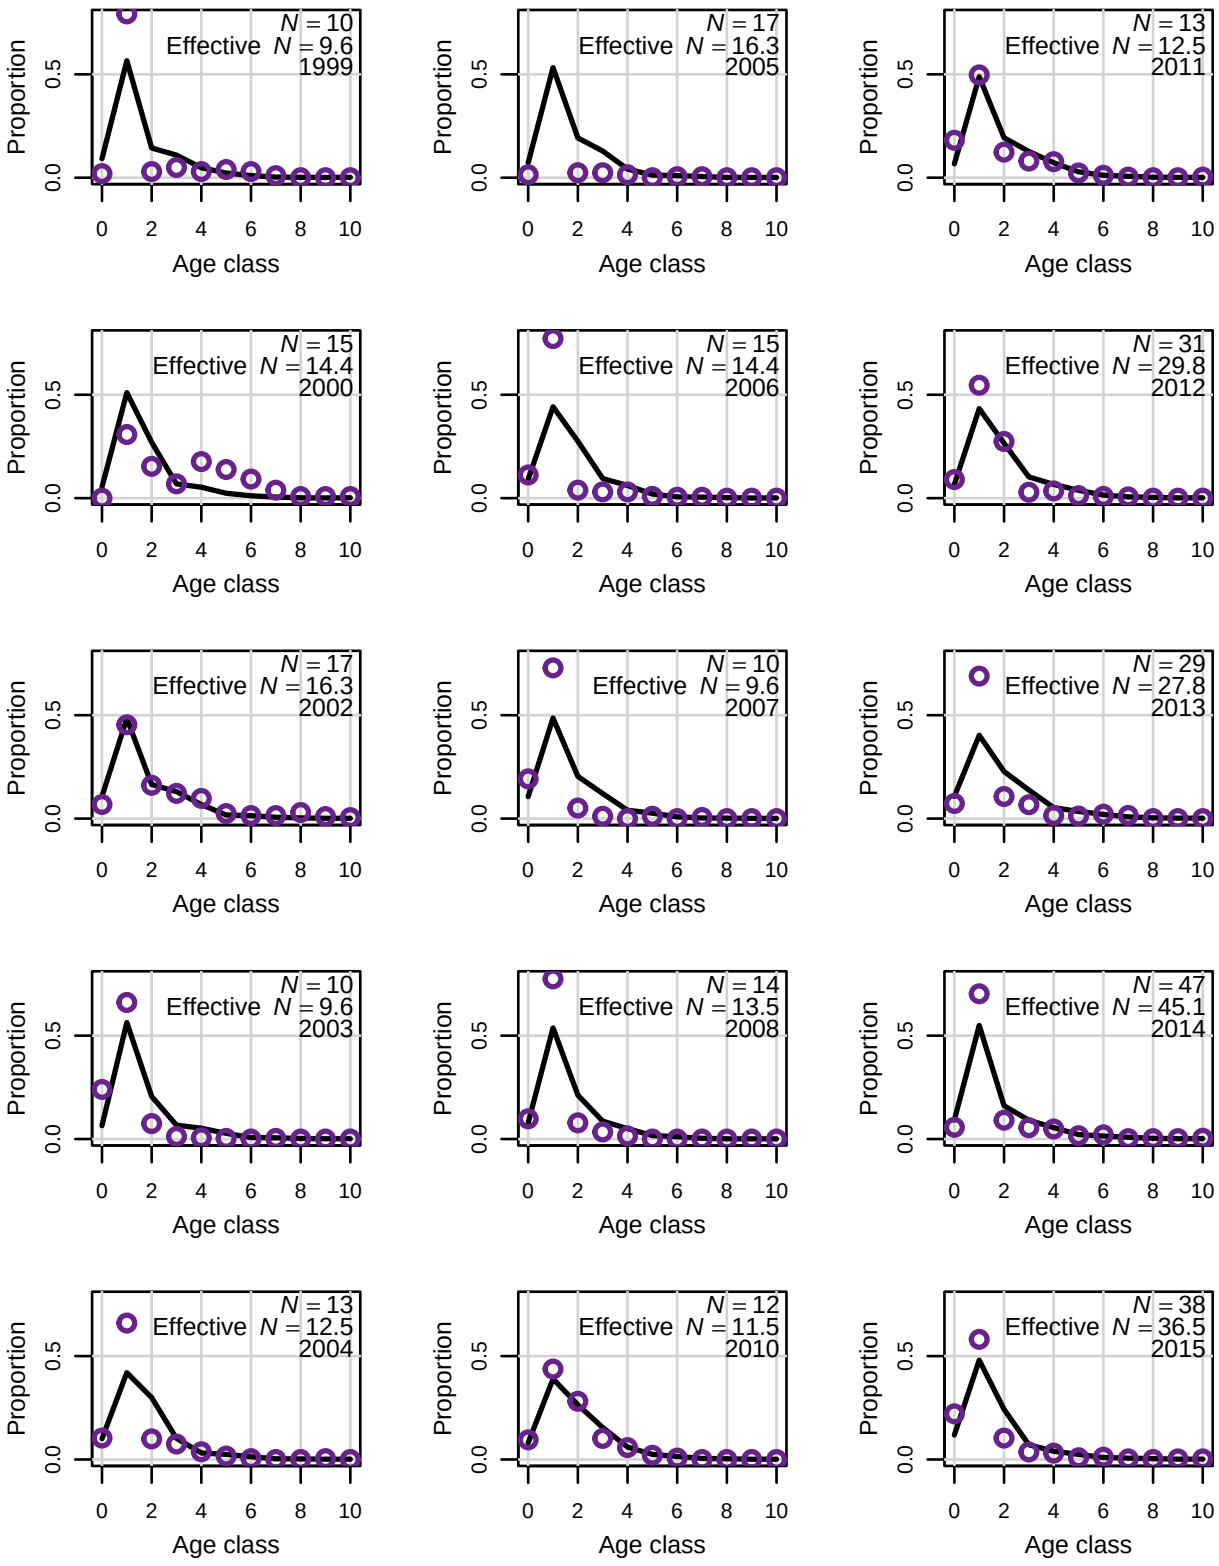

Figure 2. (cont.) Observed (open circles) and estimated (solid line) annual age compositions by fleet.

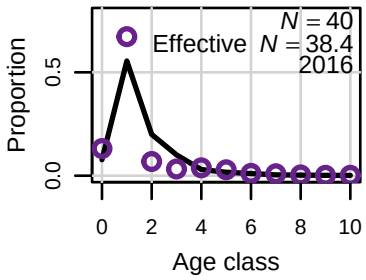

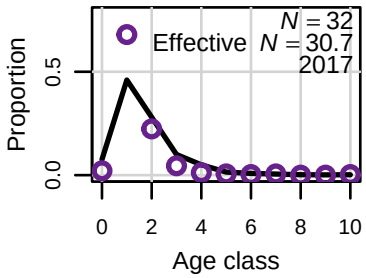

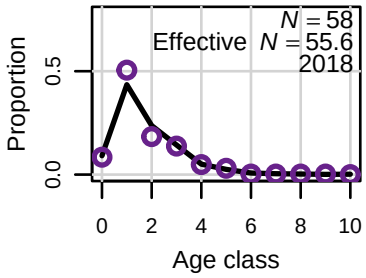

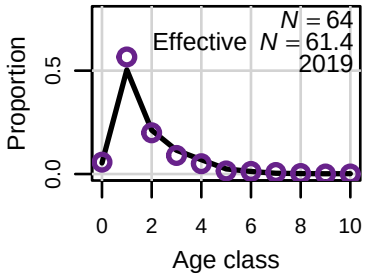

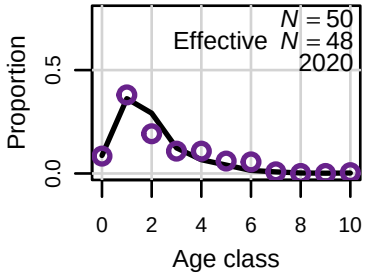

Figure 3. Top panel is a bubble plot of age composition residuals from commercial handline landings; blue represents overestimates and orange underestimates. Bottom panel shows correlation between predicted and observed values. The year is the approximate midpoint of the pooled annual compositions.

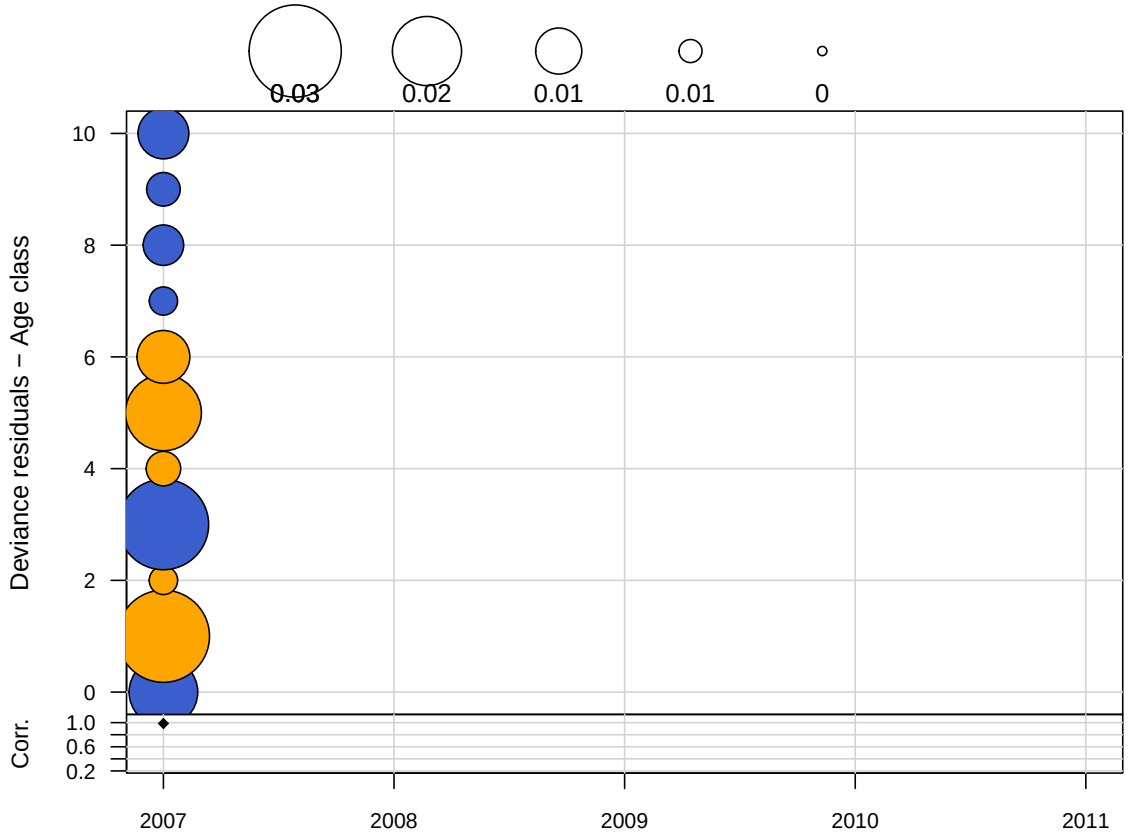

Figure 3. (cont.) Top panel is a bubble plot of age composition residuals from commercial pound net landings; blue represents overestimates and orange underestimates. Bottom panel shows correlation between predicted and observed values.

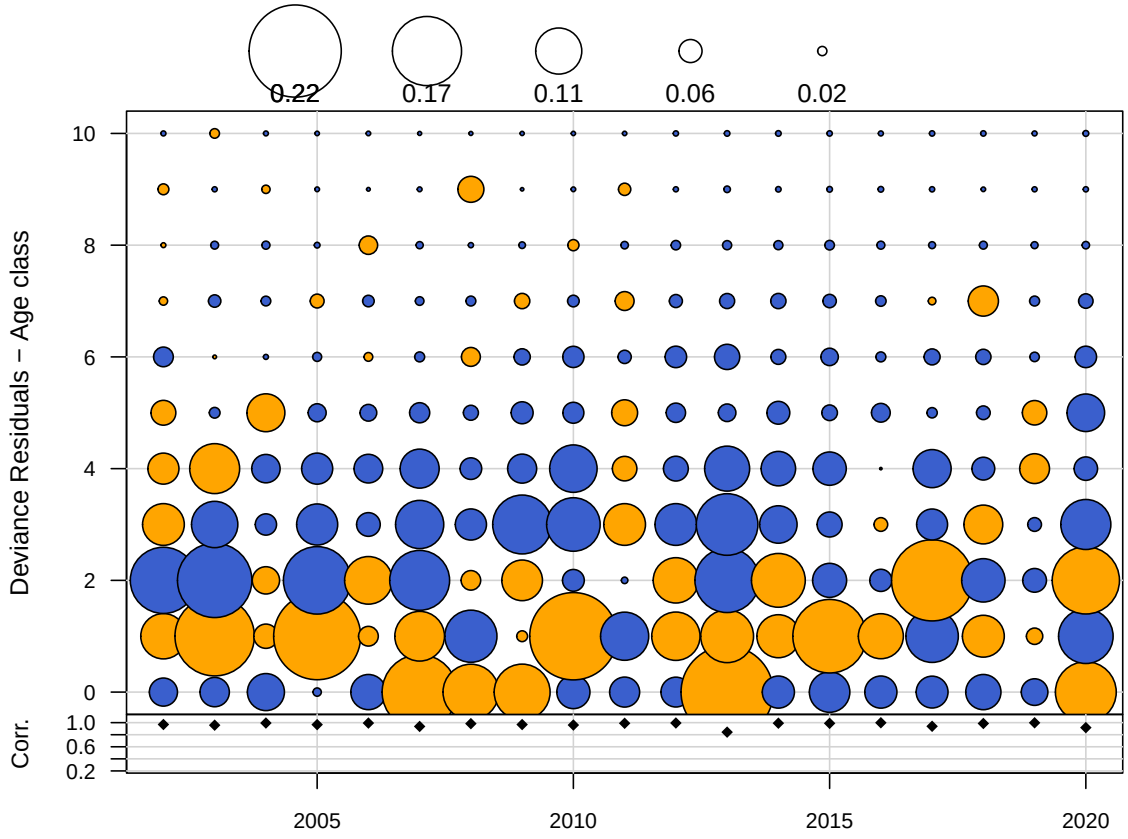

Figure 3. (cont.) Top panel is a bubble plot of age composition residuals from commercial gill net landings; blue represents overestimates and orange underestimates. Bottom panel shows correlation between predicted and observed values.

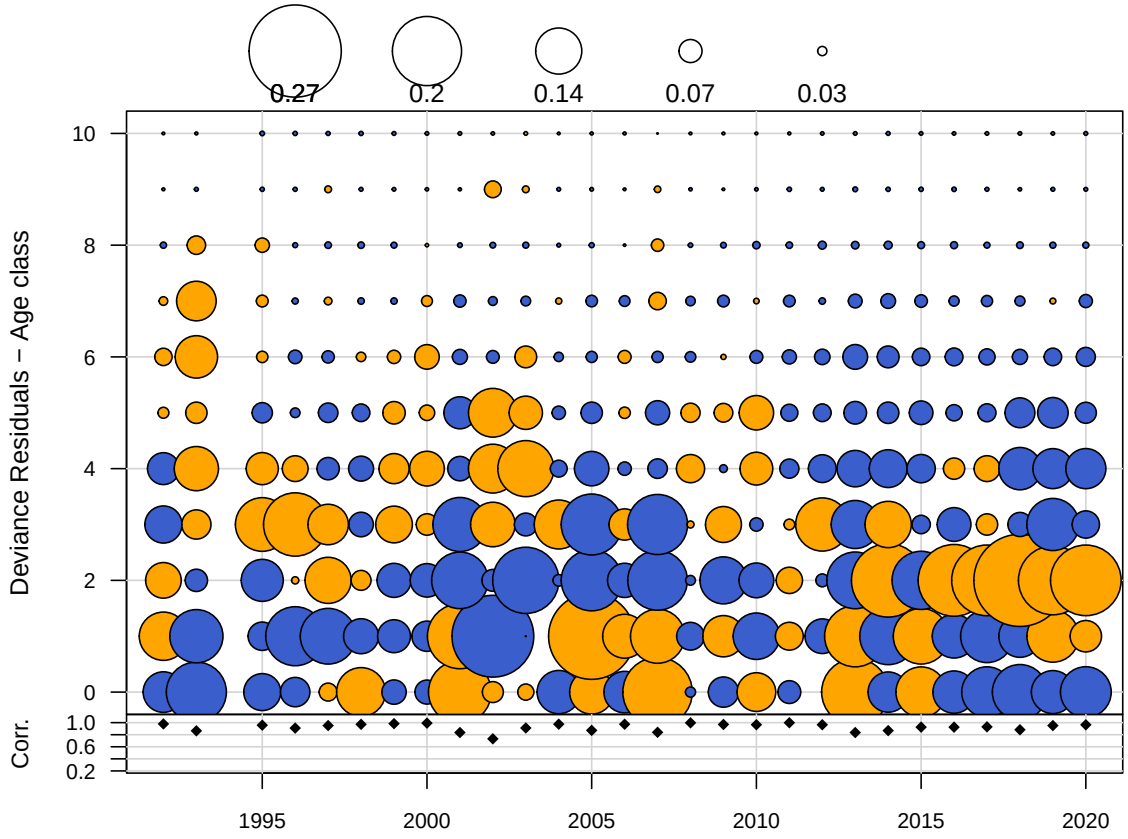

Figure 3. (cont.) Top panel is a bubble plot of age composition residuals from commercial cast net landings; blue represents overestimates and orange underestimates. Bottom panel shows correlation between predicted and observed values. The year is the approximate midpoint of the pooled annual compositions.

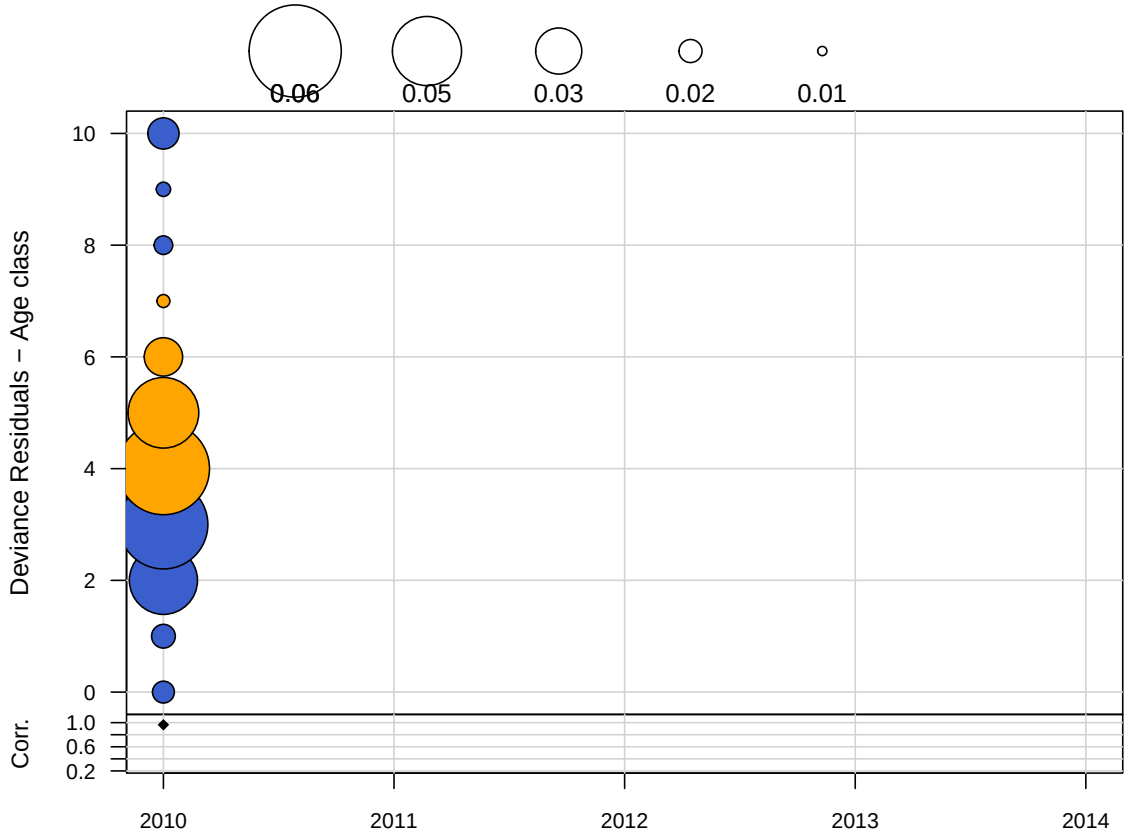

Figure 3. (cont.) Top panel is a bubble plot of age composition residuals from recreational landings; blue represents overestimates and orange underestimates. Bottom panel shows correlation between predicted and observed values.

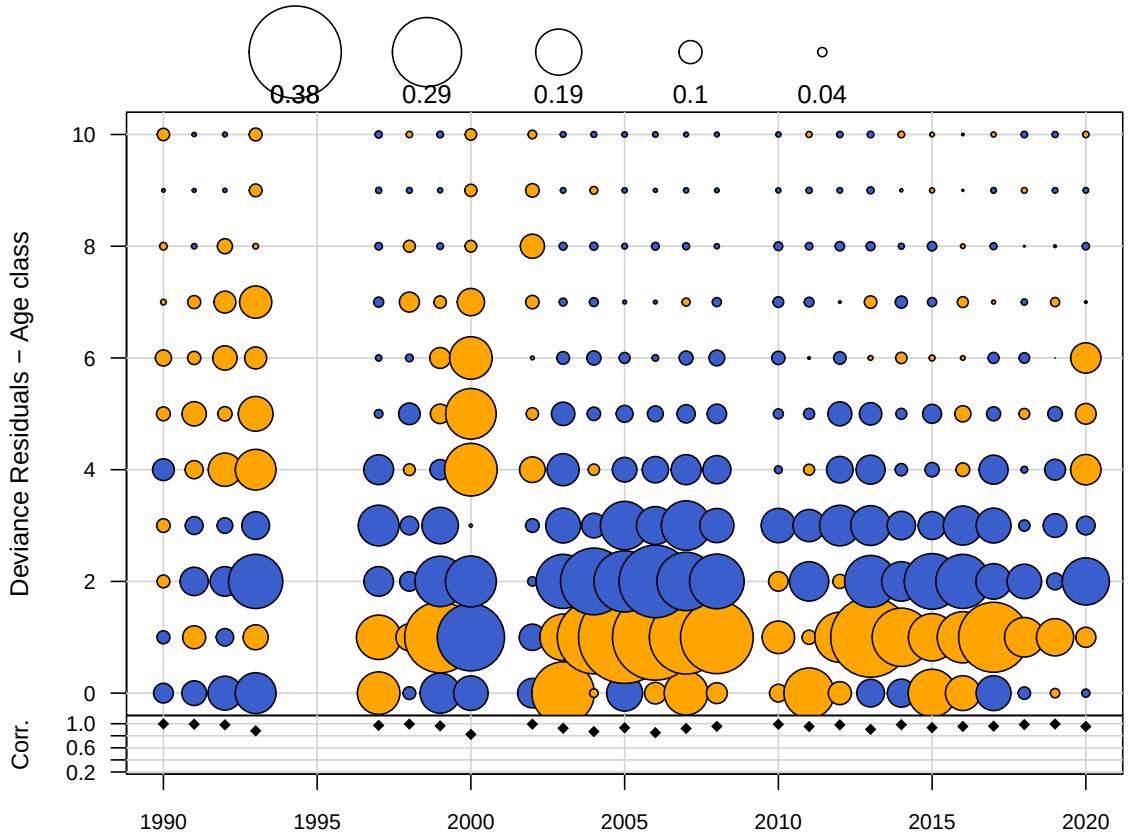

Figure 4. Observed (open circles) and estimated (line, solid circles) commercial handline landings (1000 lb whole weight).

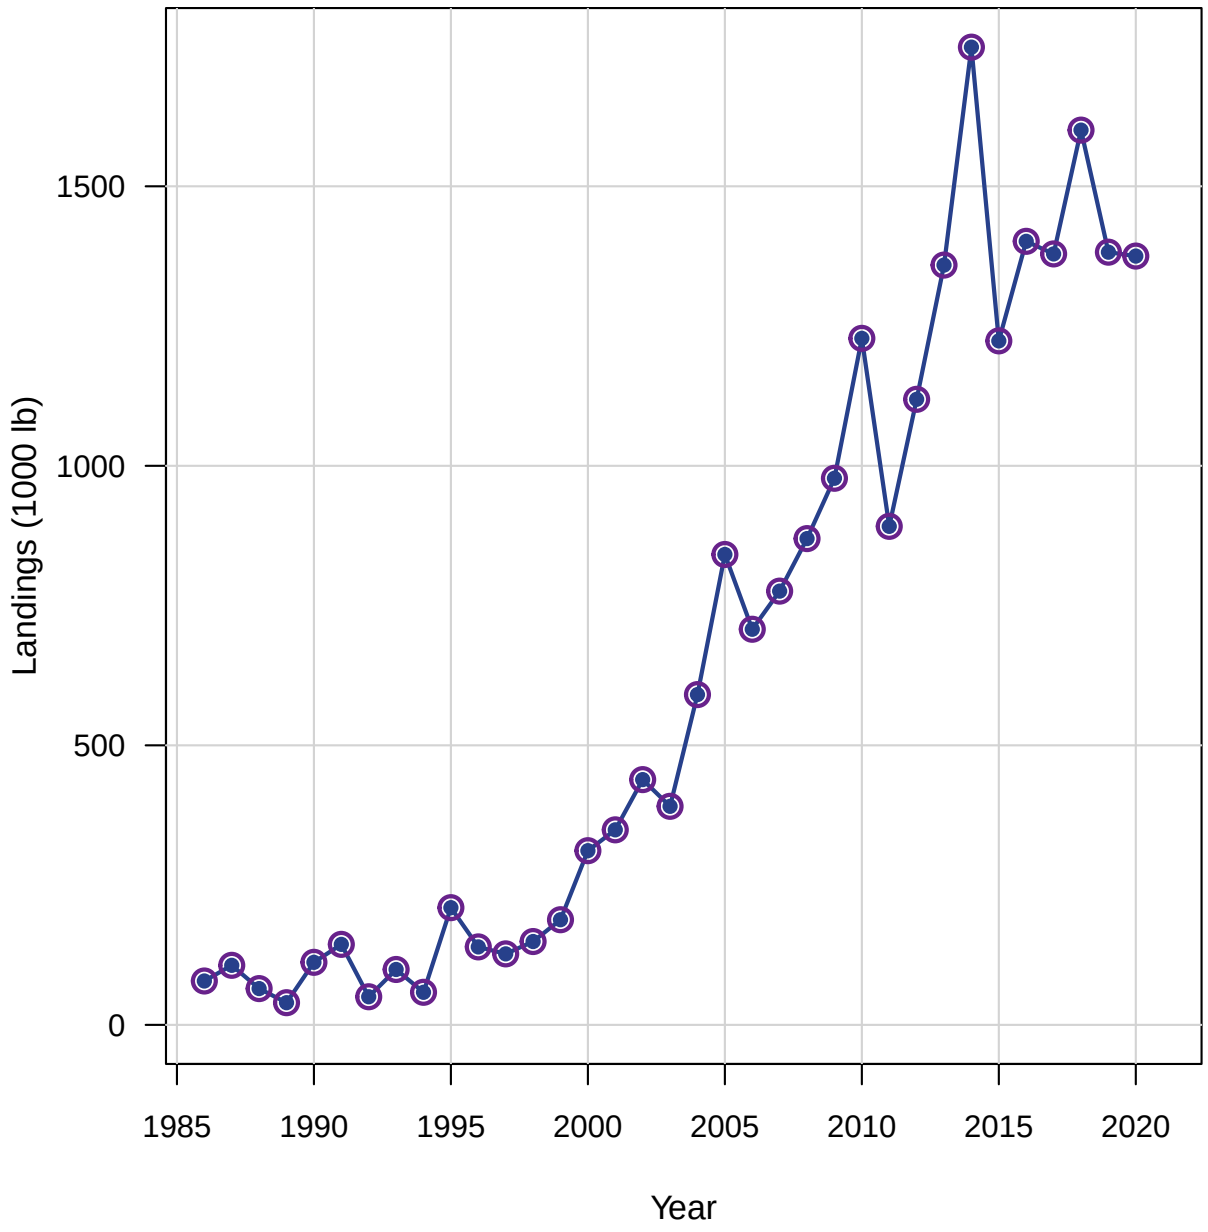

Figure 5. Observed (open circles) and estimated (line, solid circles) commercial pound net landings (1000 lb whole weight).

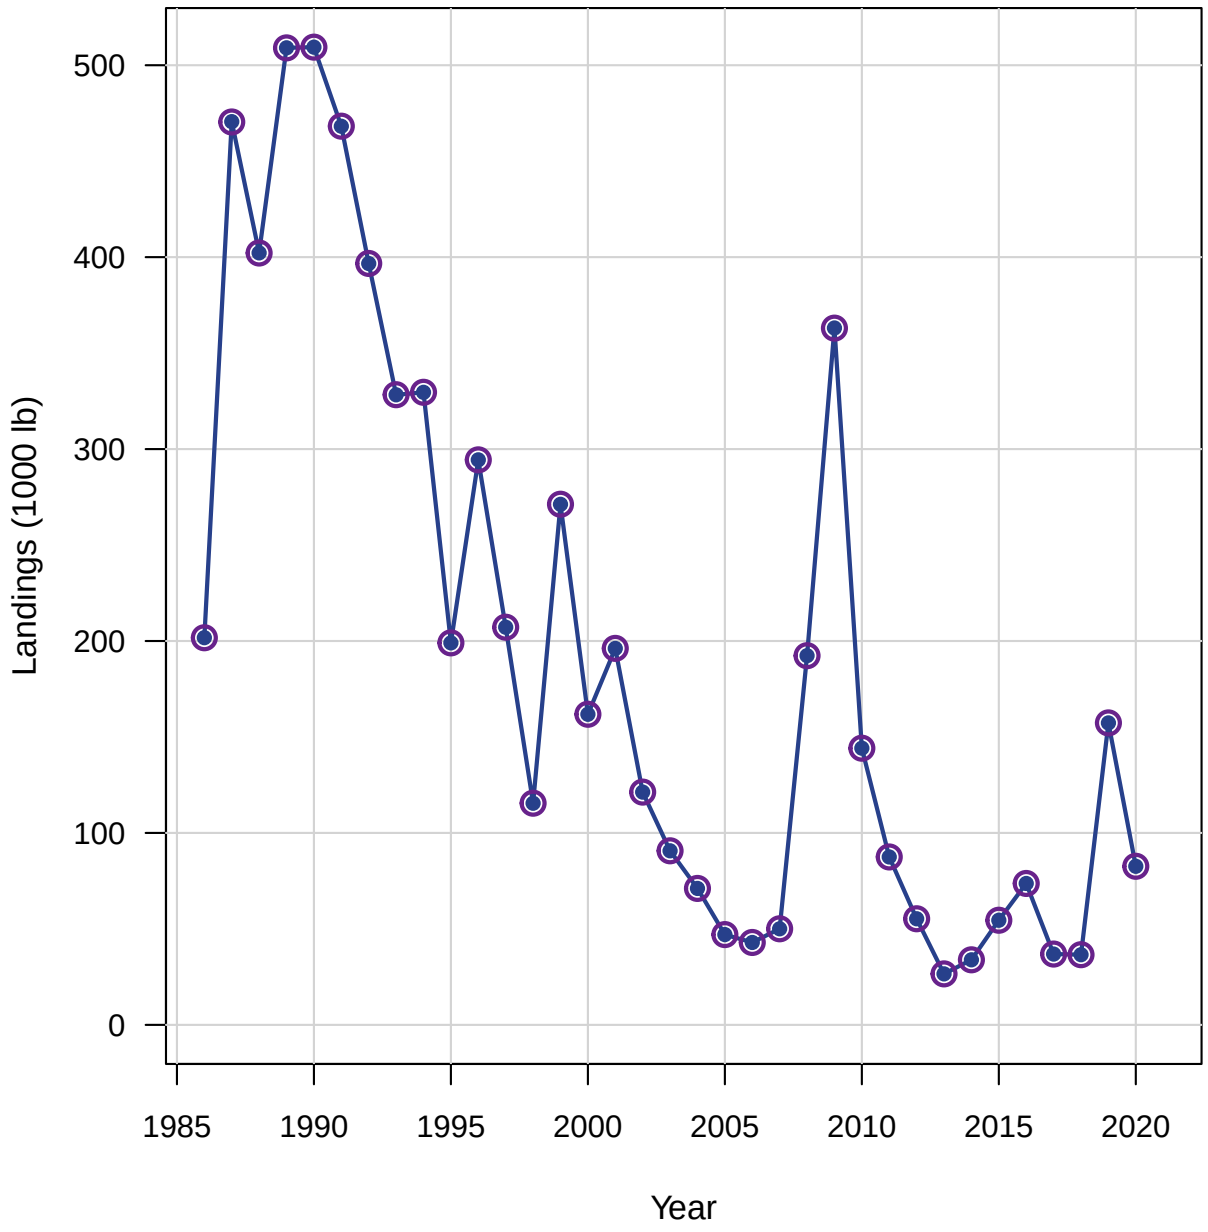

Figure 6. Observed (open circles) and estimated (line, solid circles) commercial gillnet landings (1000 lb whole weight).

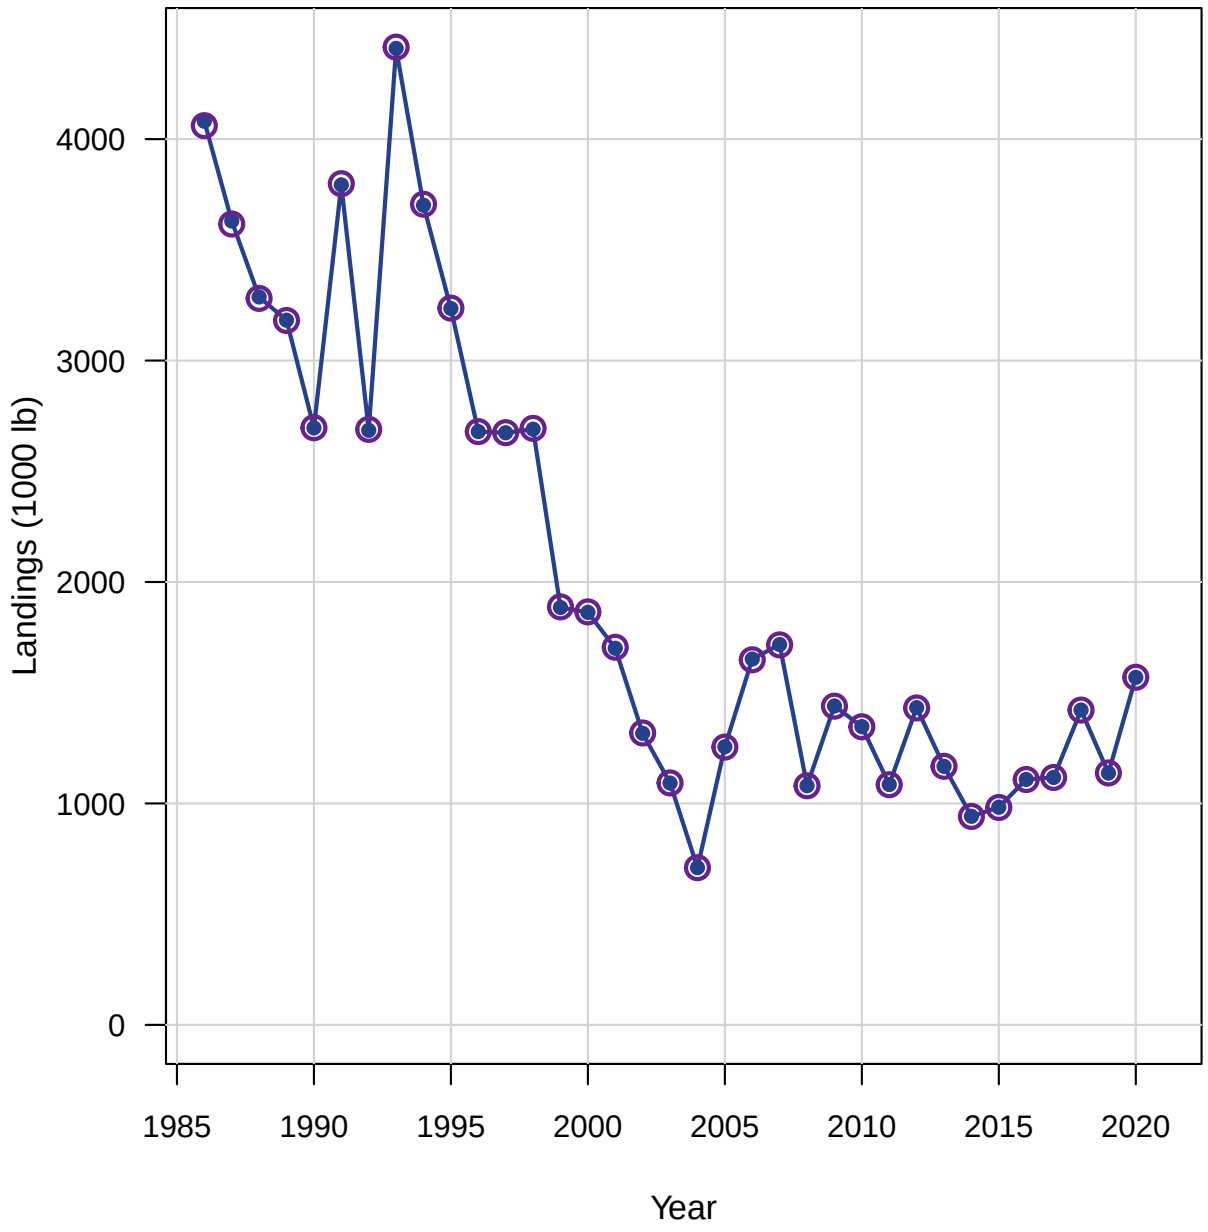

Figure 7. Observed (open circles) and estimated (line, solid circles) commercial cast net landings (1000 lb whole weight).

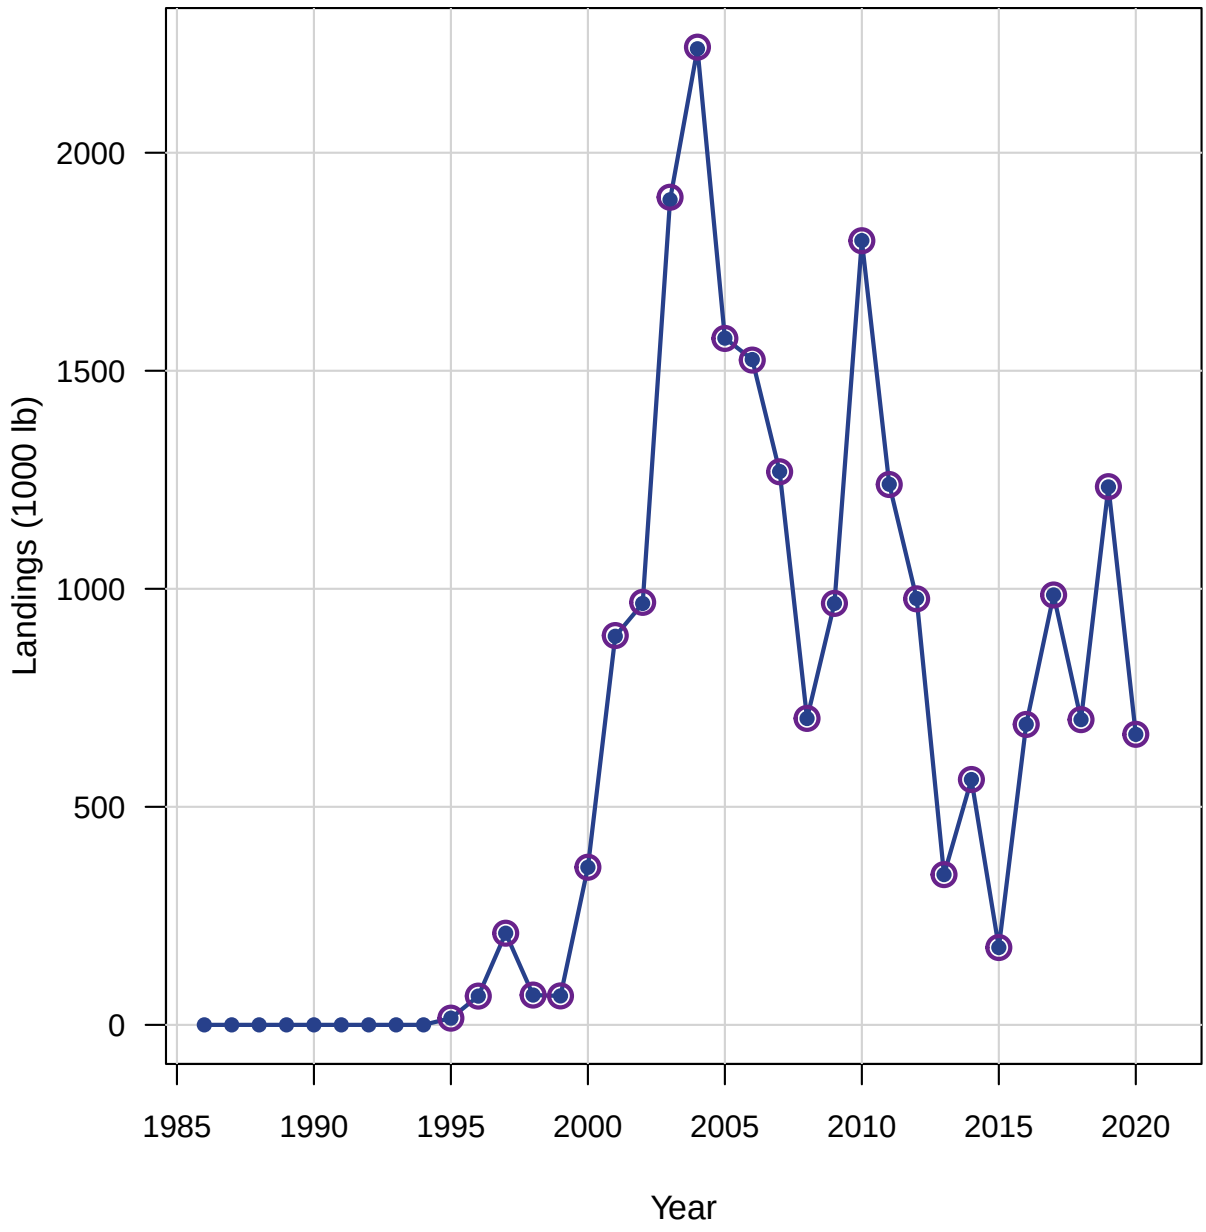

Figure 8. Observed (open circles) and estimated (line, solid circles) recreational landings (1000 fish).

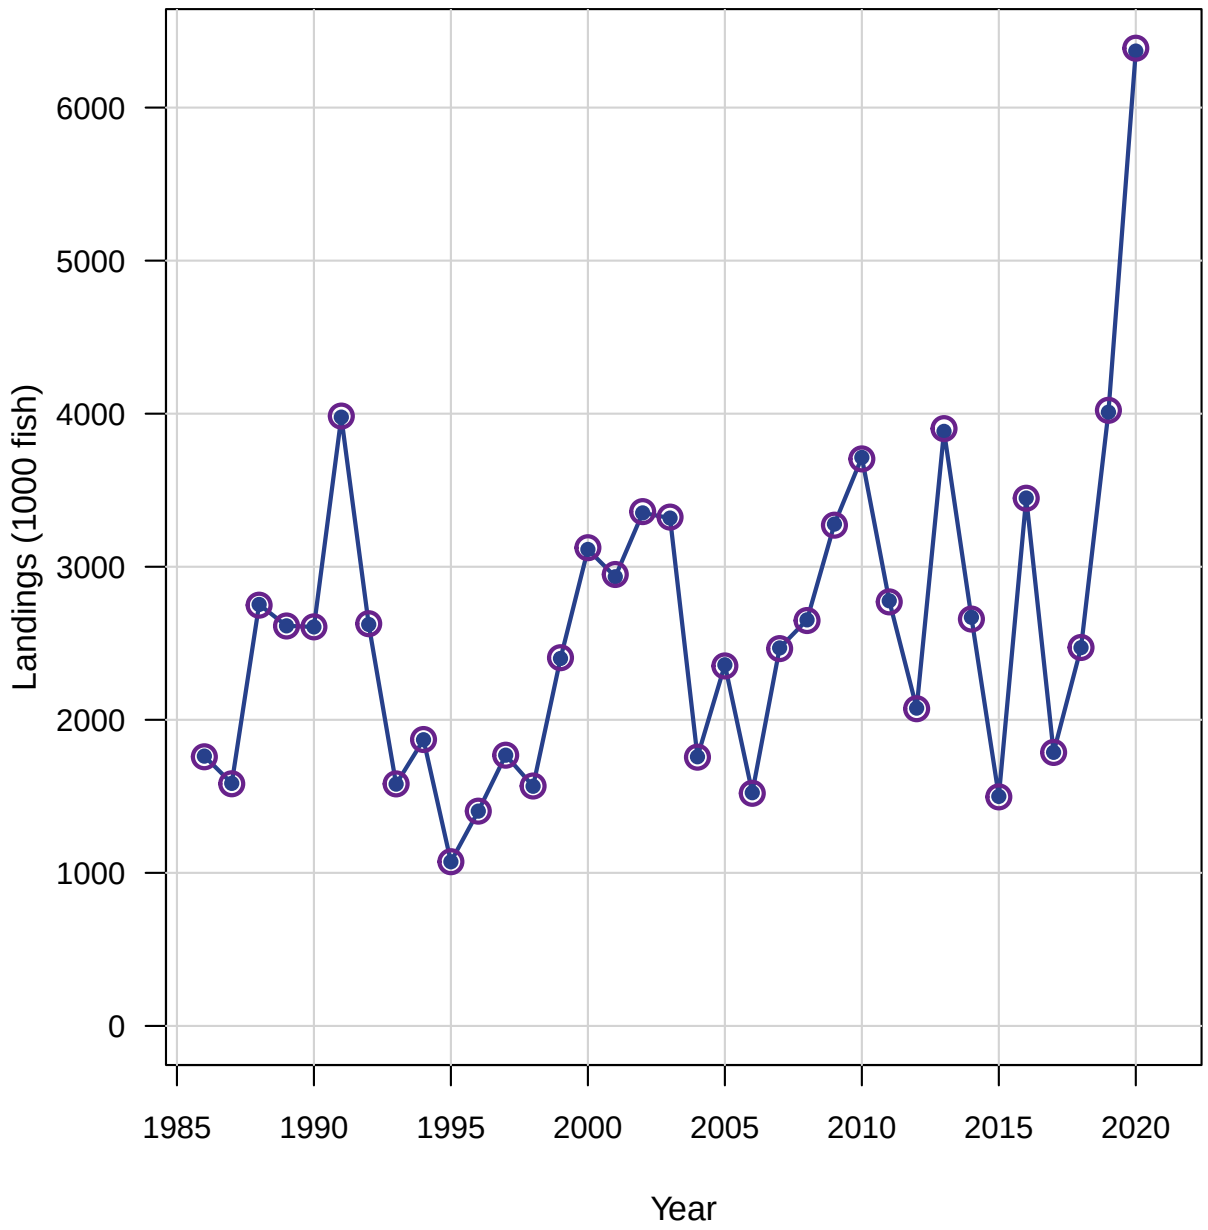

Figure 9. Observed (open circles) and estimated (line, solid circles) recreational discards (1000 fish).

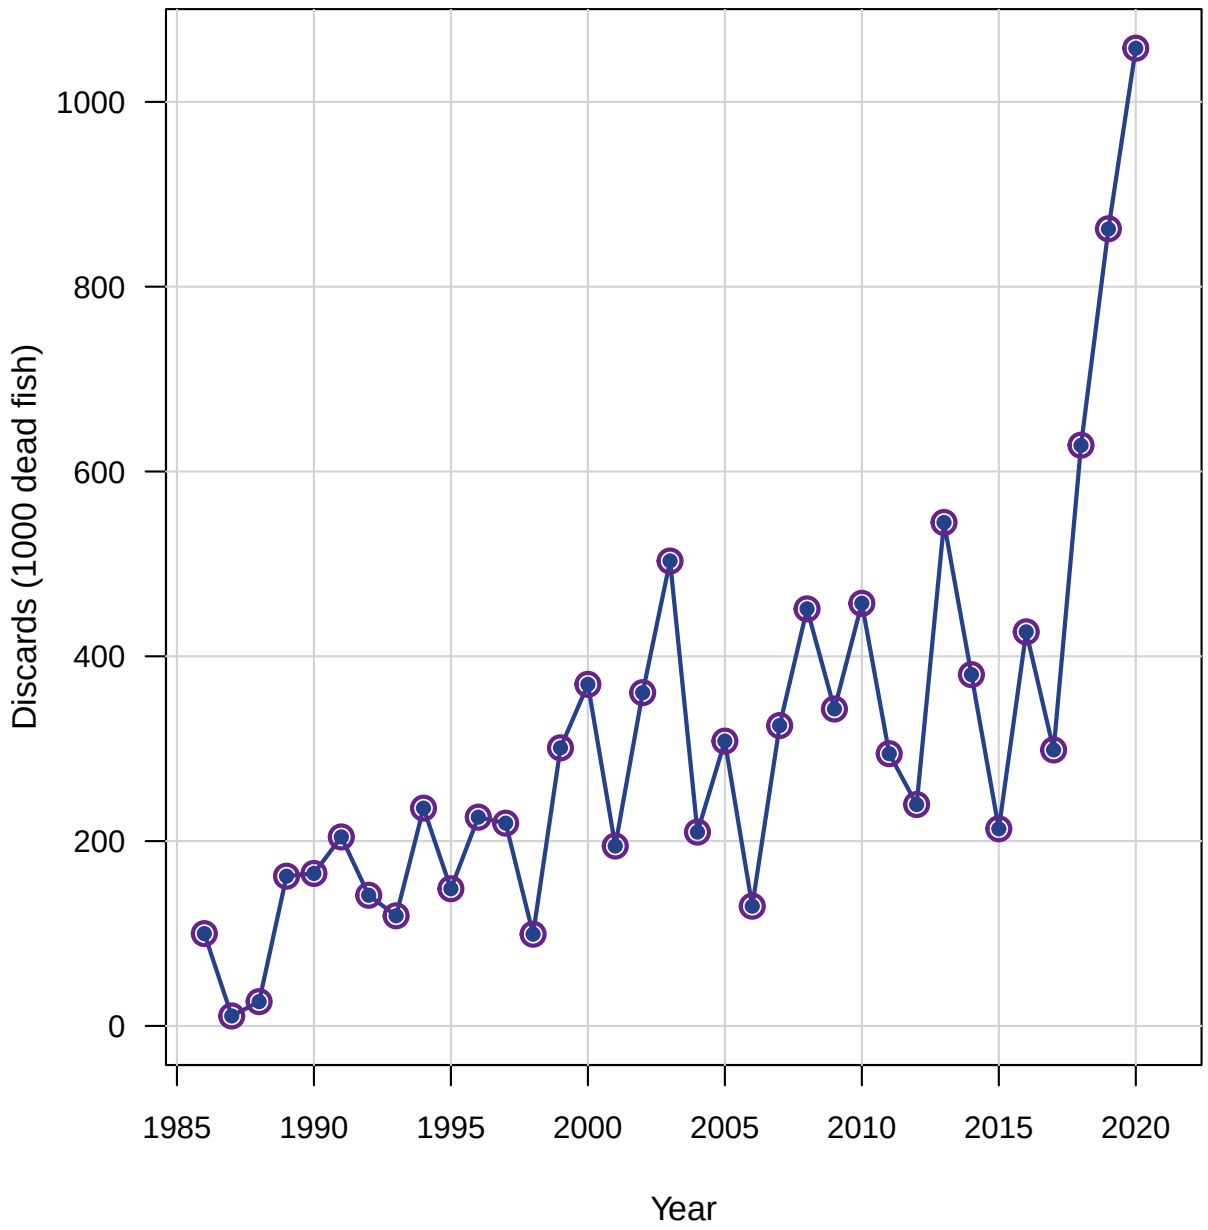

Figure 10. Observed (open circles) and estimated (line, solid circles) discards from shrimp bycatch (1000 fish).

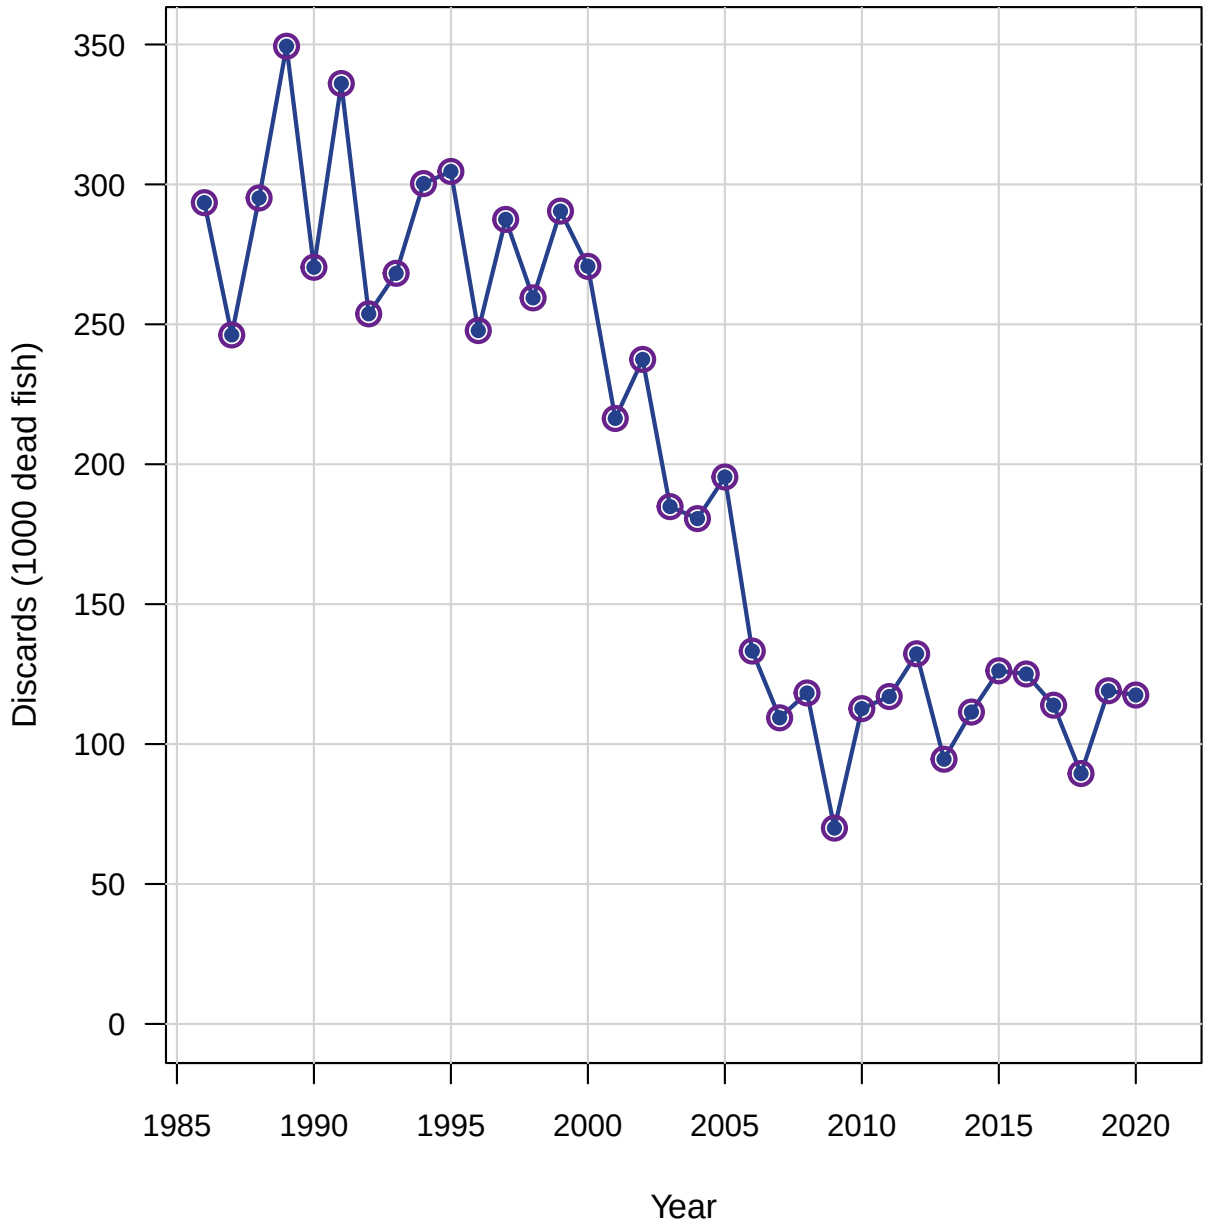

Figure 11. Top Panel: Observed (open circles) and estimated (line, solid circles) index of abundance from Florida commercial handline trip tickets. Bottom panel: Scaled residuals of estimated index of abundance. The model input CVs were modified from the input values by the SDNR weights.

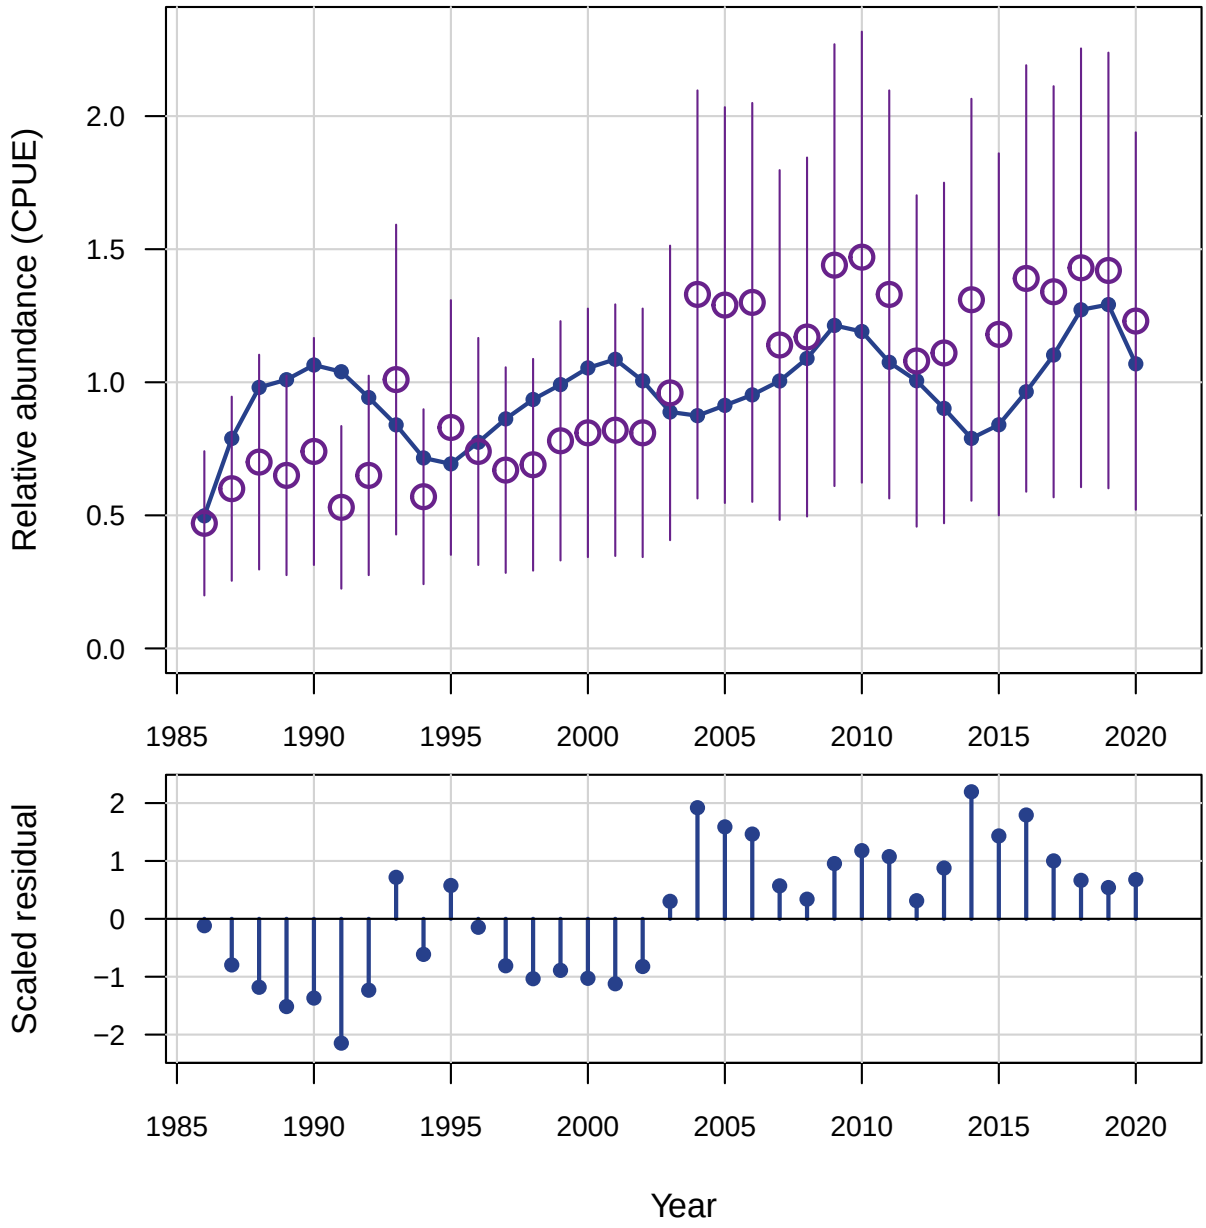

Figure 12. Top Panel: Observed (open circles) and estimated (line, solid circles) index of abundance from MRIP harvested fish. Bottom panel: Scaled residuals of estimated index of abundance. The model input CVs were modified from the input values by the SDNR weights.

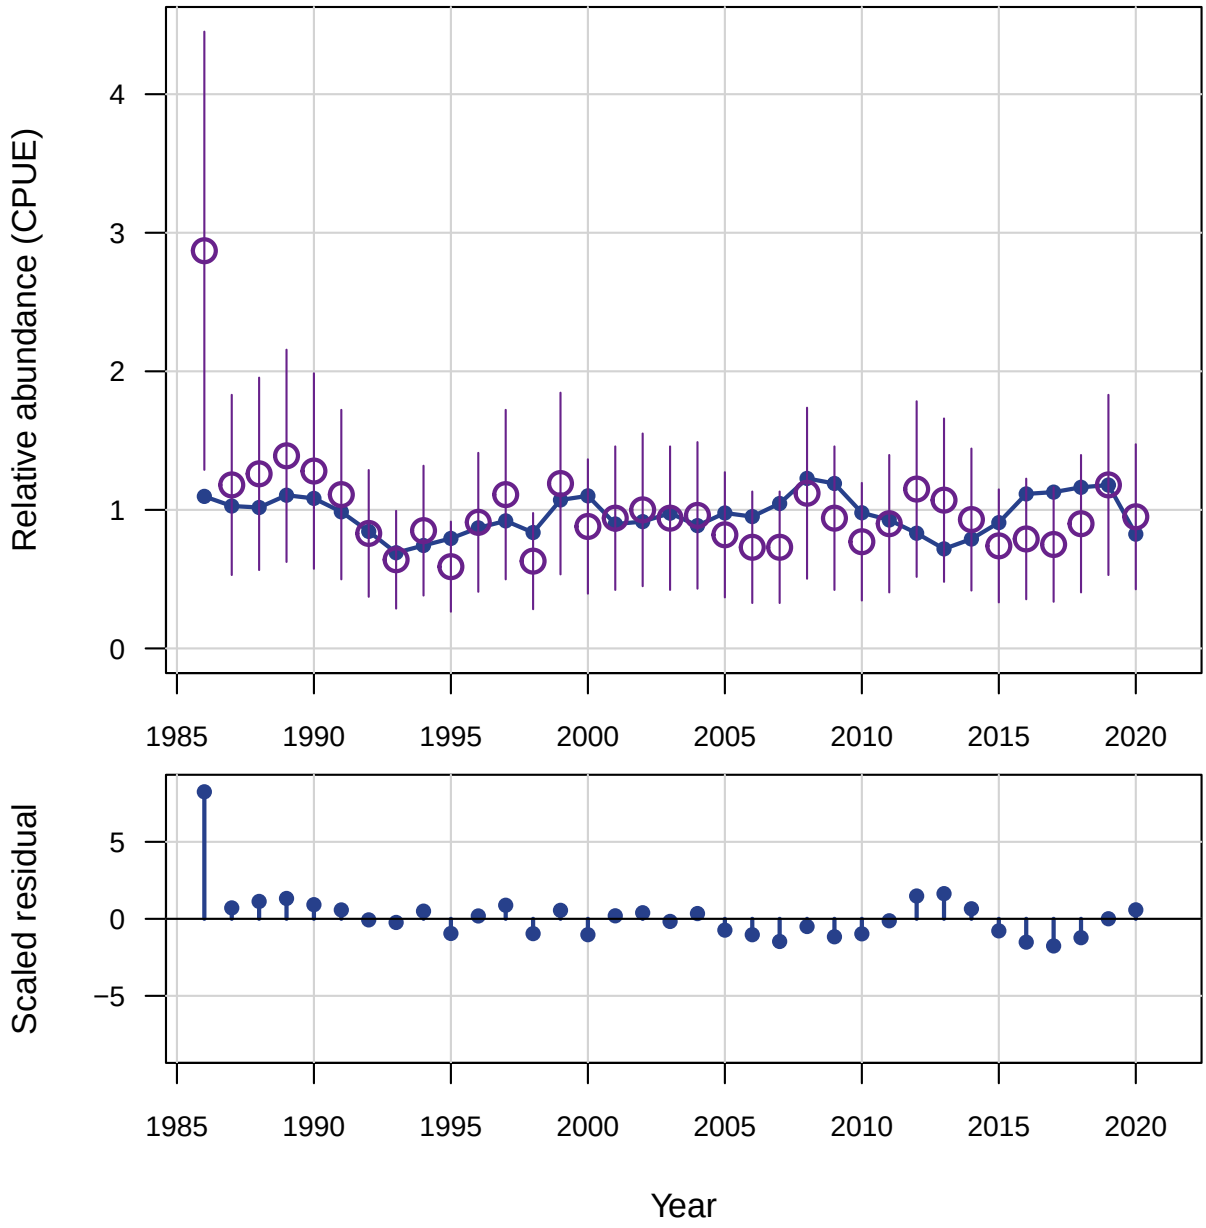

Figure 13. Top Panel: Observed (open circles) and estimated (line, solid circles) index of abundance from SEAMAP YOY samples. Bottom panel: Scaled residuals of estimated index of abundance. The model input CVs were modified from the input values by the SDNR weights.

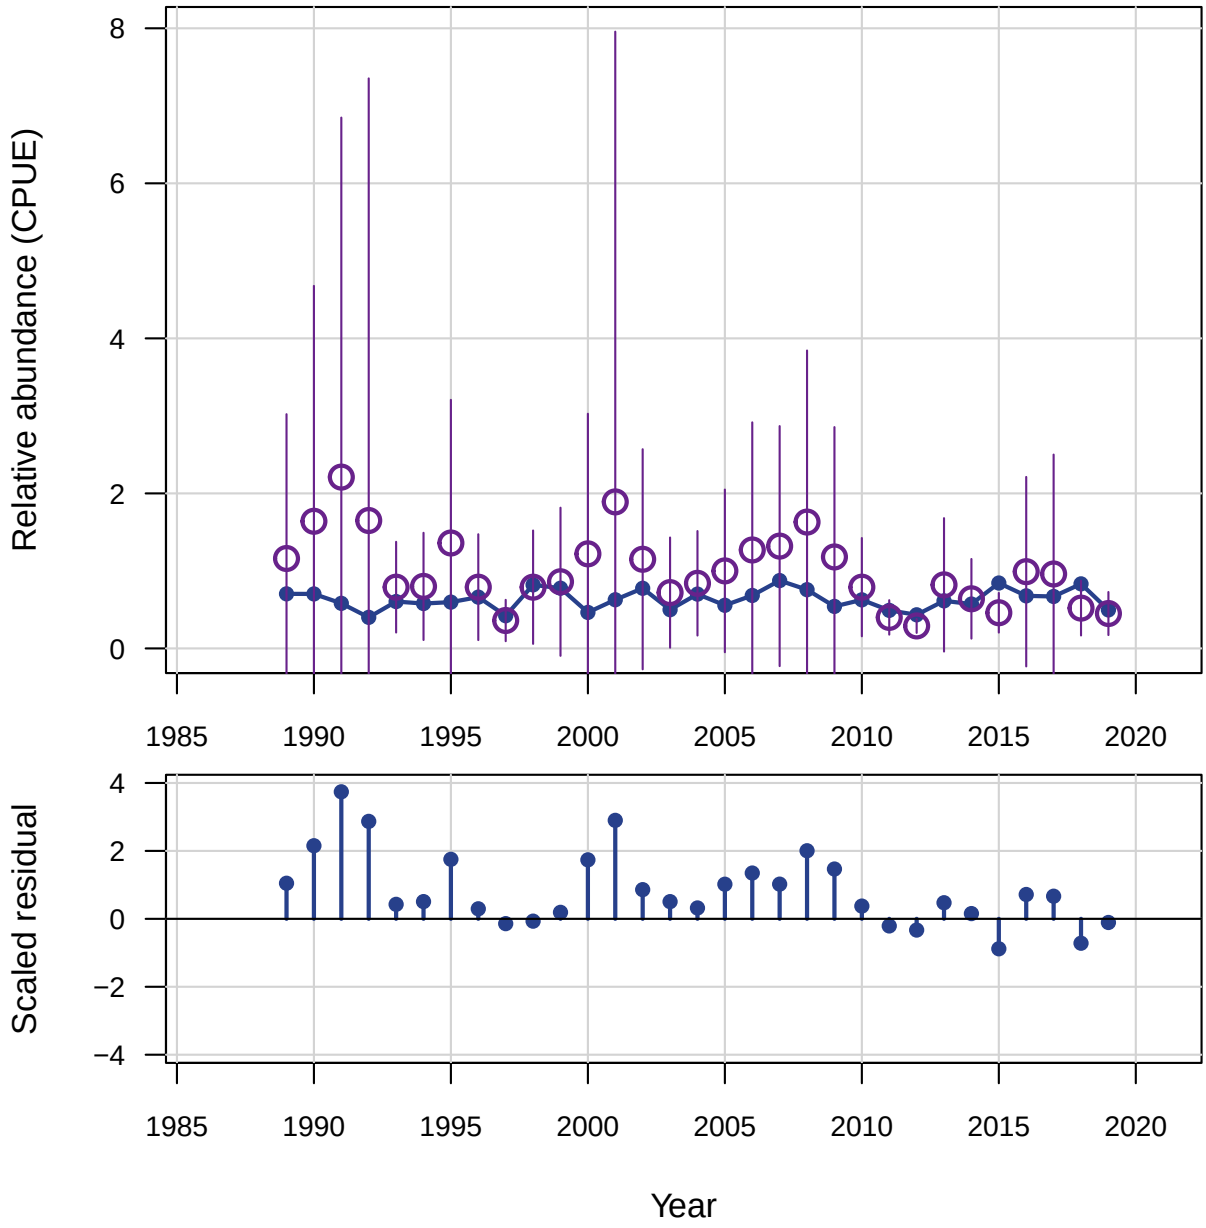

Figure 14. Estimated abundance at age at start of year.

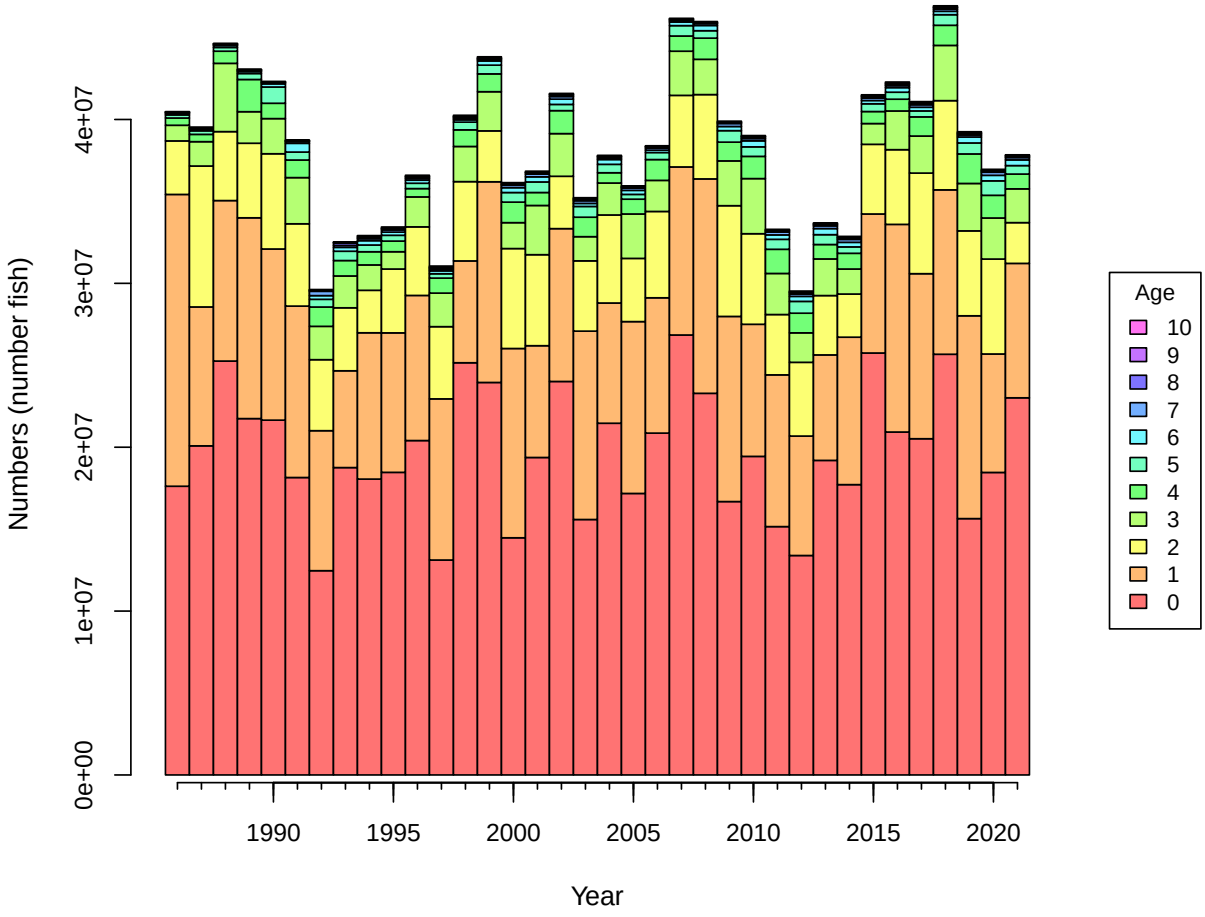

Figure 15. Top panel: Estimated recruitment of age-0 fish. Horizontal dashed line indicates R_{MSY}. Bottom panel: log recruitment residuals.

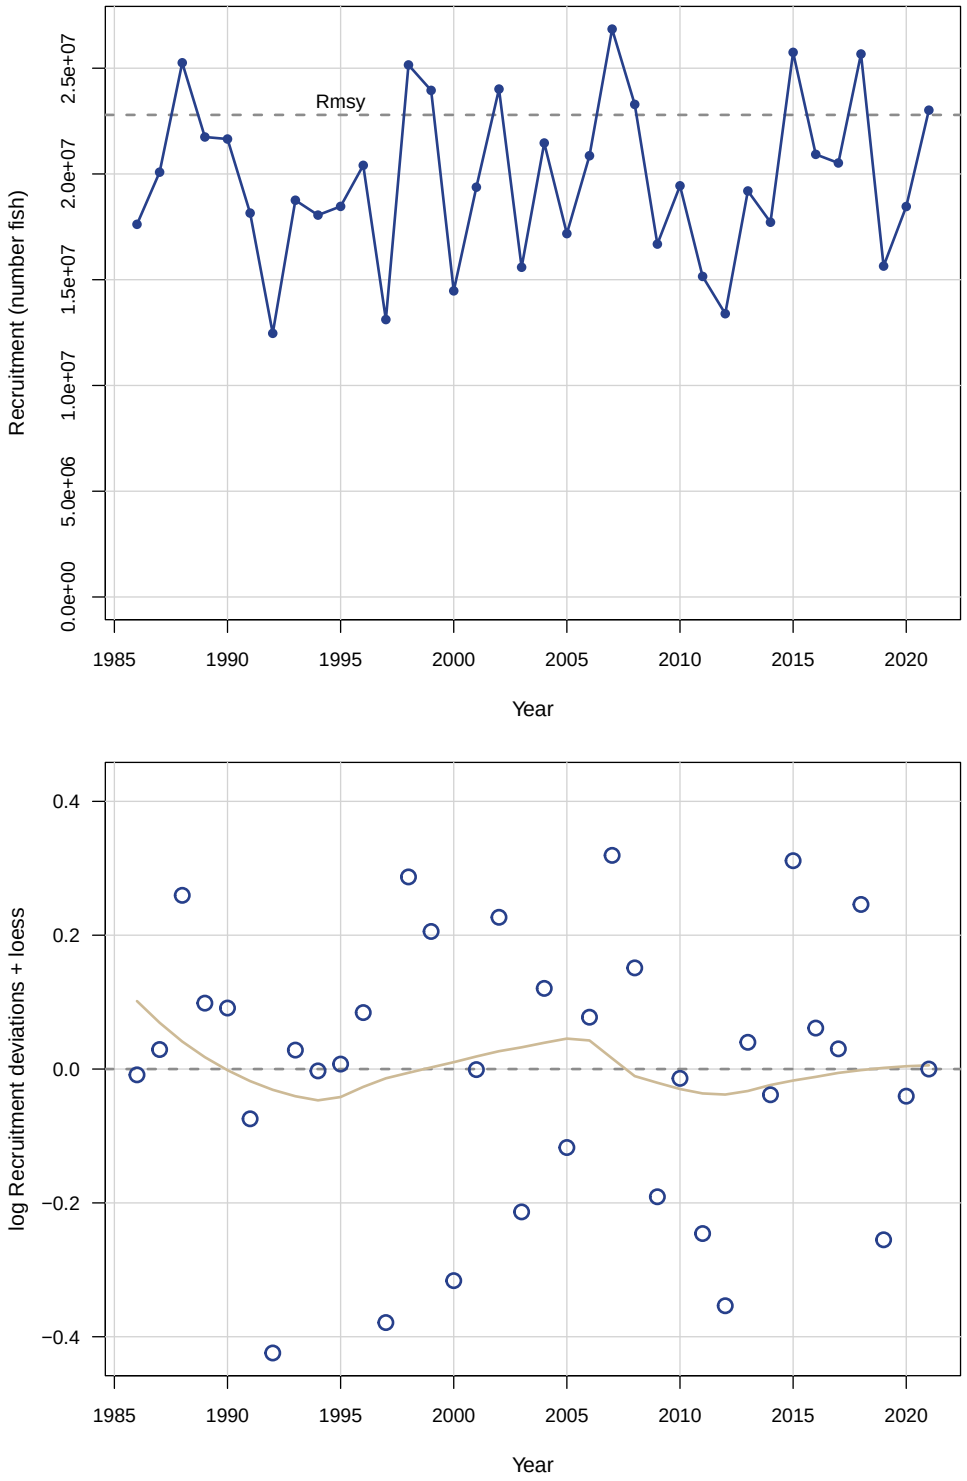

Figure 16. Estimated biomass at age at start of year.

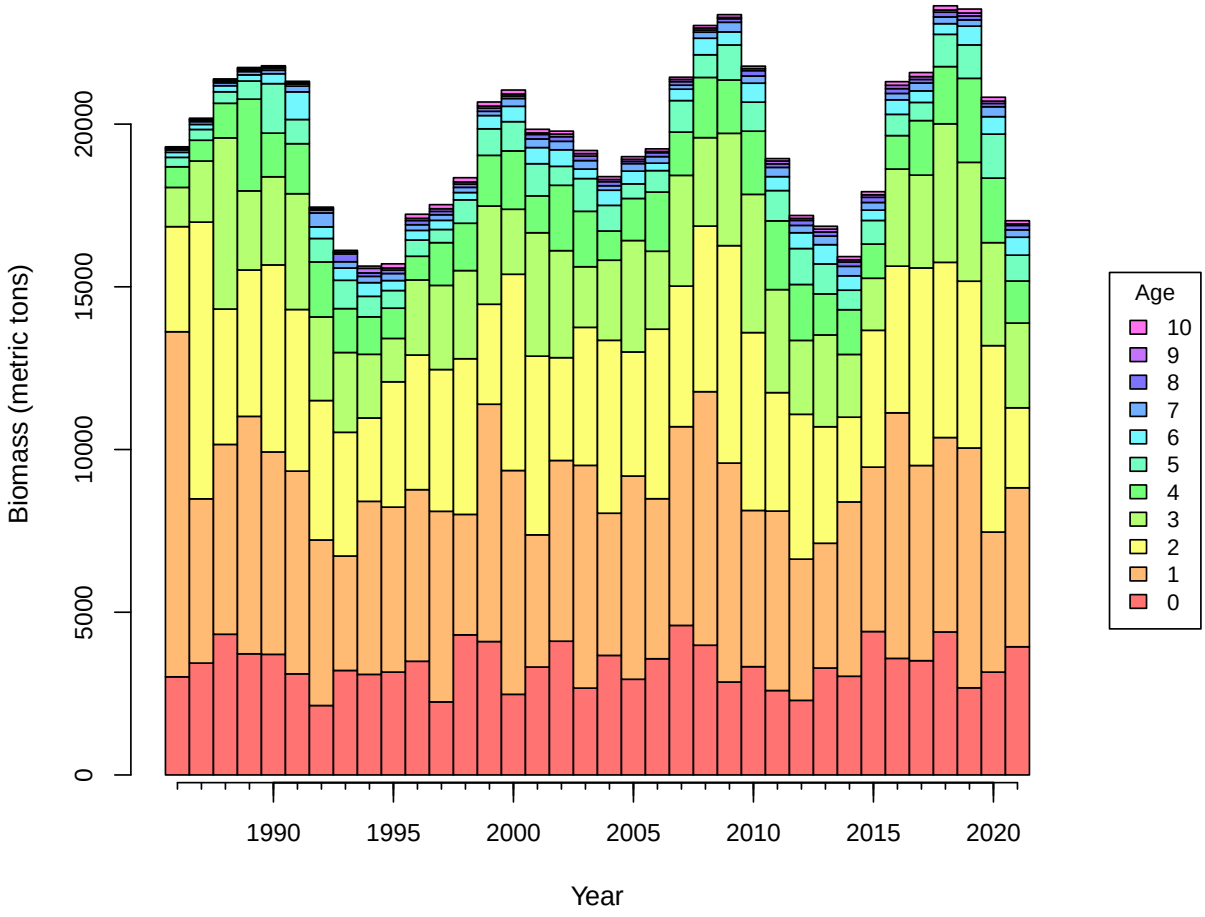

Figure 17. Selectivity of commercial handline fleet for all years in the model. Year indicates start year of the model.

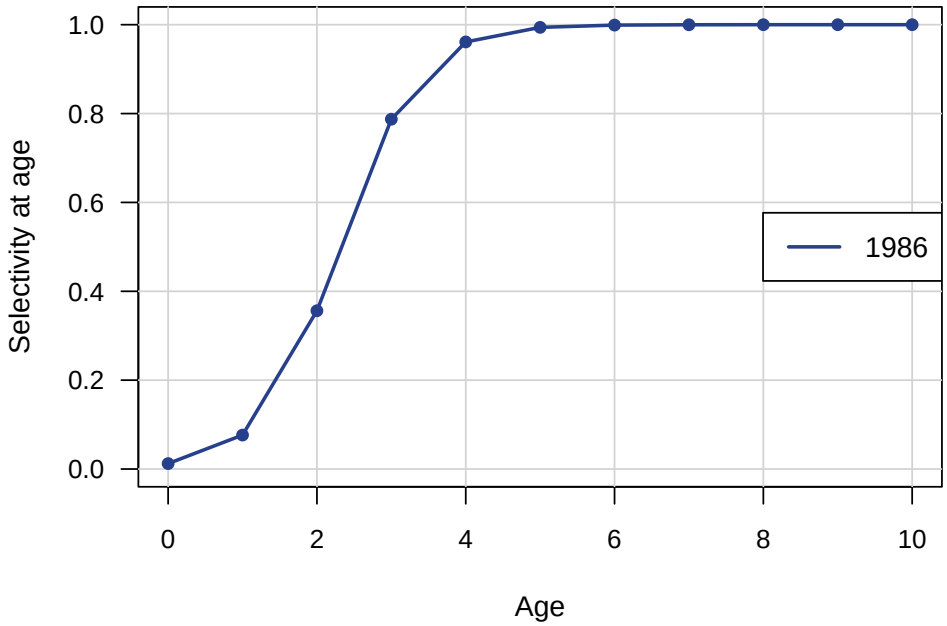

Figure 18. Selectivity of commercial pound net fleet for all years in the model. Year indicates start year of the model.

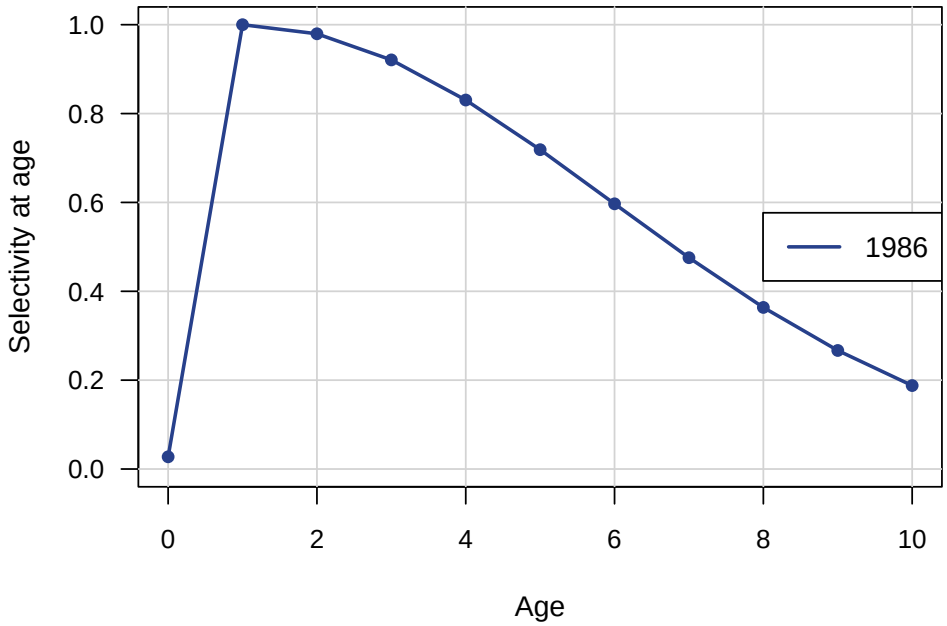

Figure 19. Selectivity of commercial gillnet fleet for all years in the model. Year indicates start year of the model.

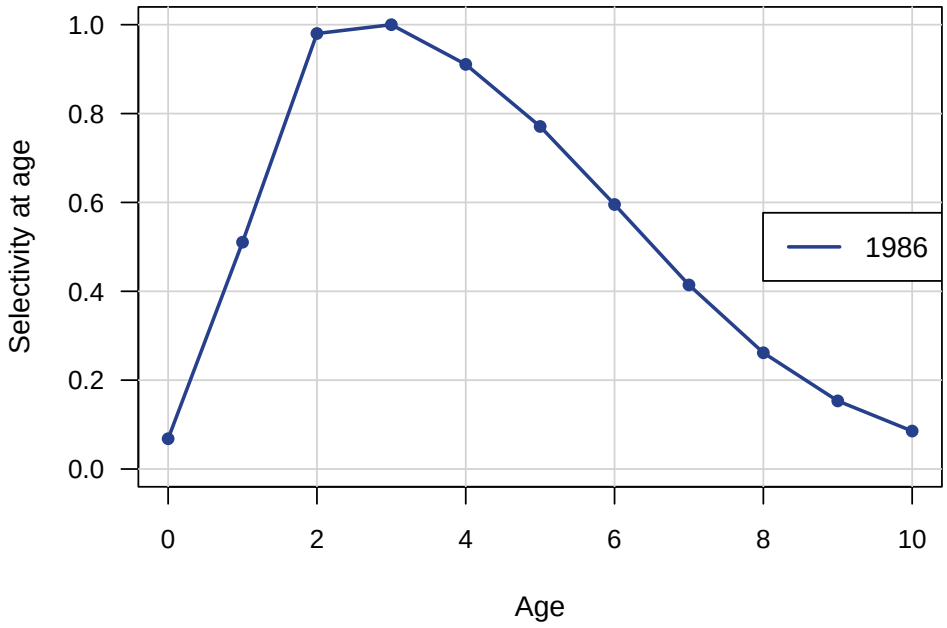

Figure 20. Selectivities of commercial cast net fleet for all years in the model. Year indicates start year of the model.

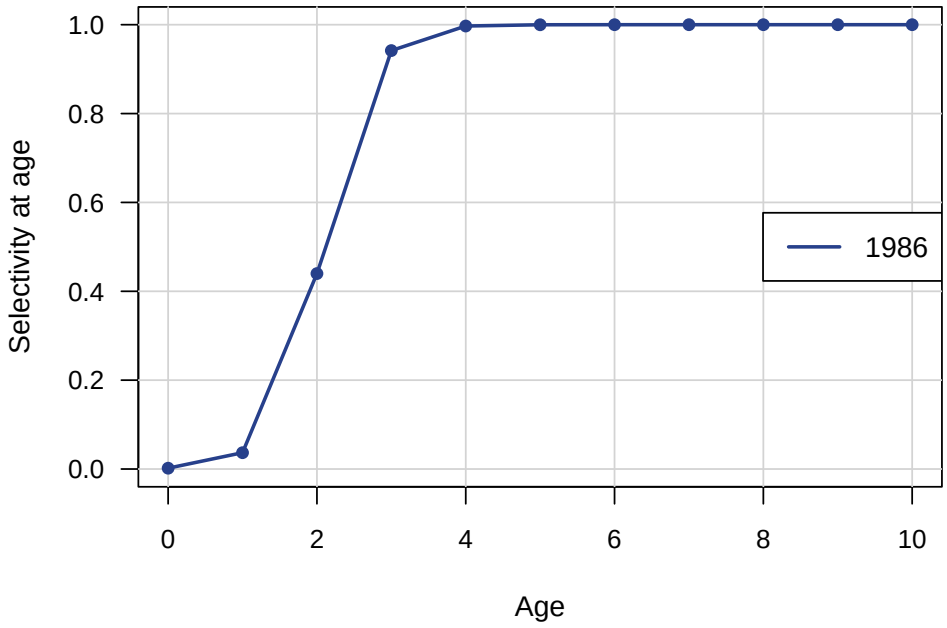

Figure 21. Selectivities of general recreational fishery for all years in the model. Year indicates start year of the model.

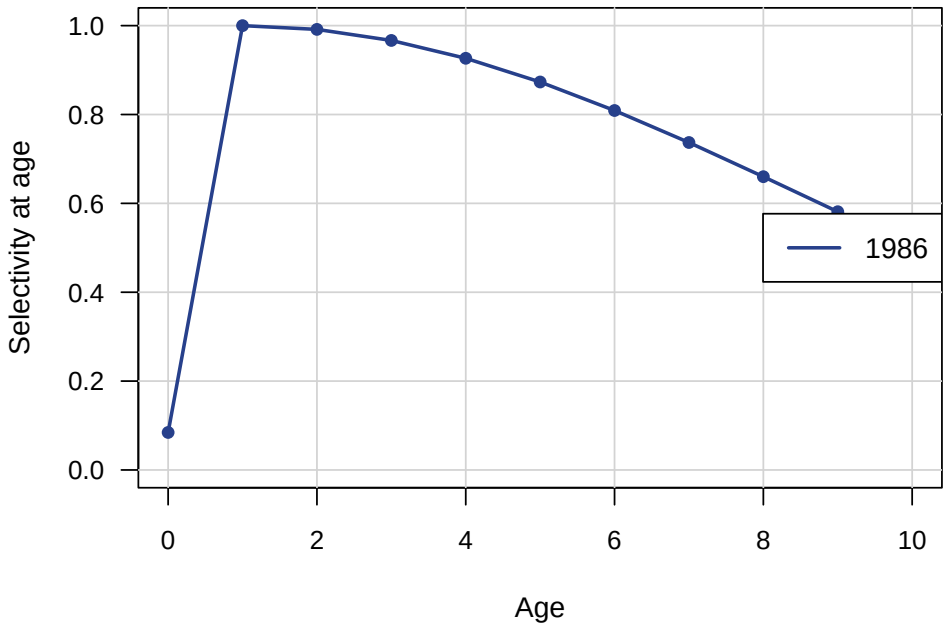

Figure 22. Selectivities of recreational discard for all years in the model. Year indicates start year of the model.

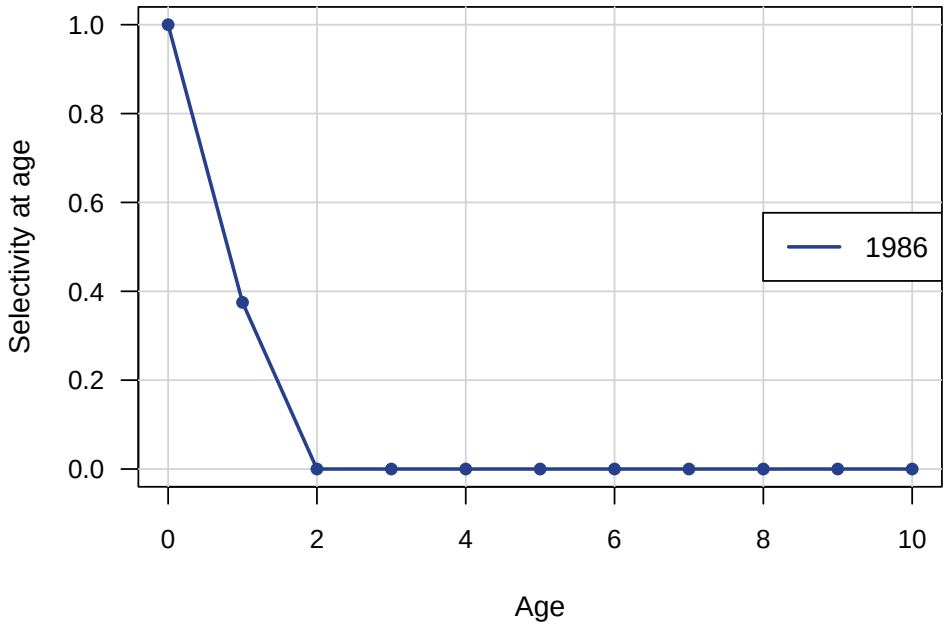

Figure 23. Selectivities of shrimp fishery discard for all years in the model. Year indicates start year of the model.

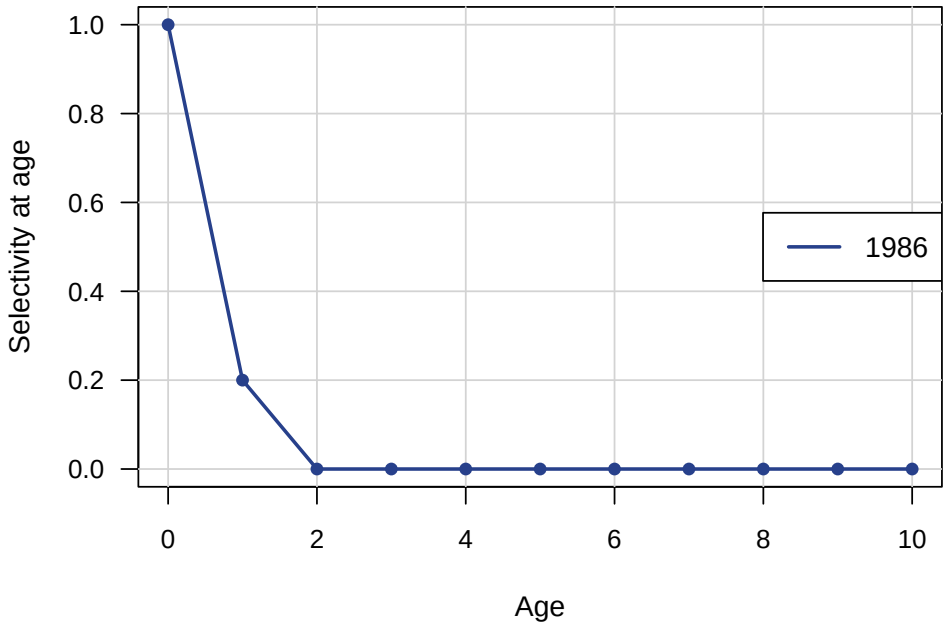

Figure 24. Average selectivity from the terminal assessment year weighted by geometric mean Fs from the last three assessment years for landings (top panel) and discards (bottom panel), and used in computation of benchmarks and central-tendency projections.

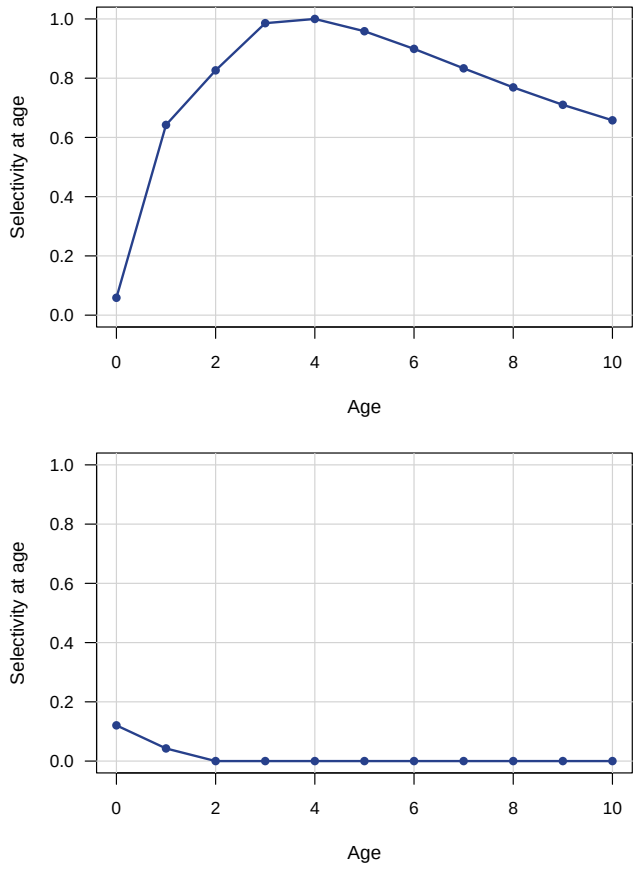

Figure 25. Estimated fully selected fishing mortality rate (per year) by fishery. cH refers to commercial handline, cP to commercial pound net, cG to commercial gill net, cC to commercial cast net, GR for recreational, GR.D for recreational discards, and SB.D for shrimp bycatch. Full F, the maximum F at age summed across fleets, may not equal the sum of fully selected F's because of dome-shaped selectivities.

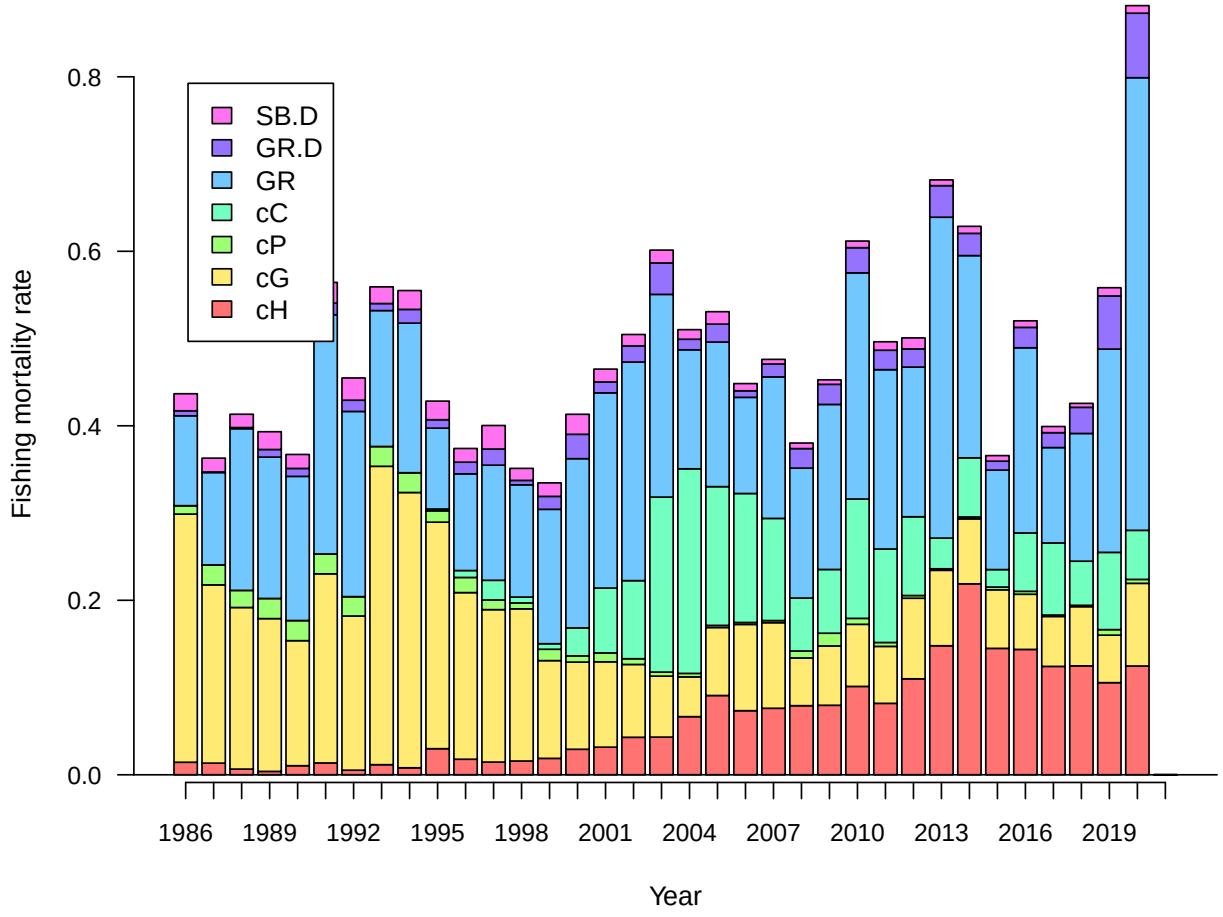

Figure 26. Alternative measures of fishing intensity. Top panel shows equilibrium SPR conditional on annual F, with a reference line at equilibrium MSY*. Bottom panel shows exploitation rate (E) computed as number killed divided total abundance (thick black curve), which can be divided into its components of landings (thin green curve) and dead discards (thin blue curve).*

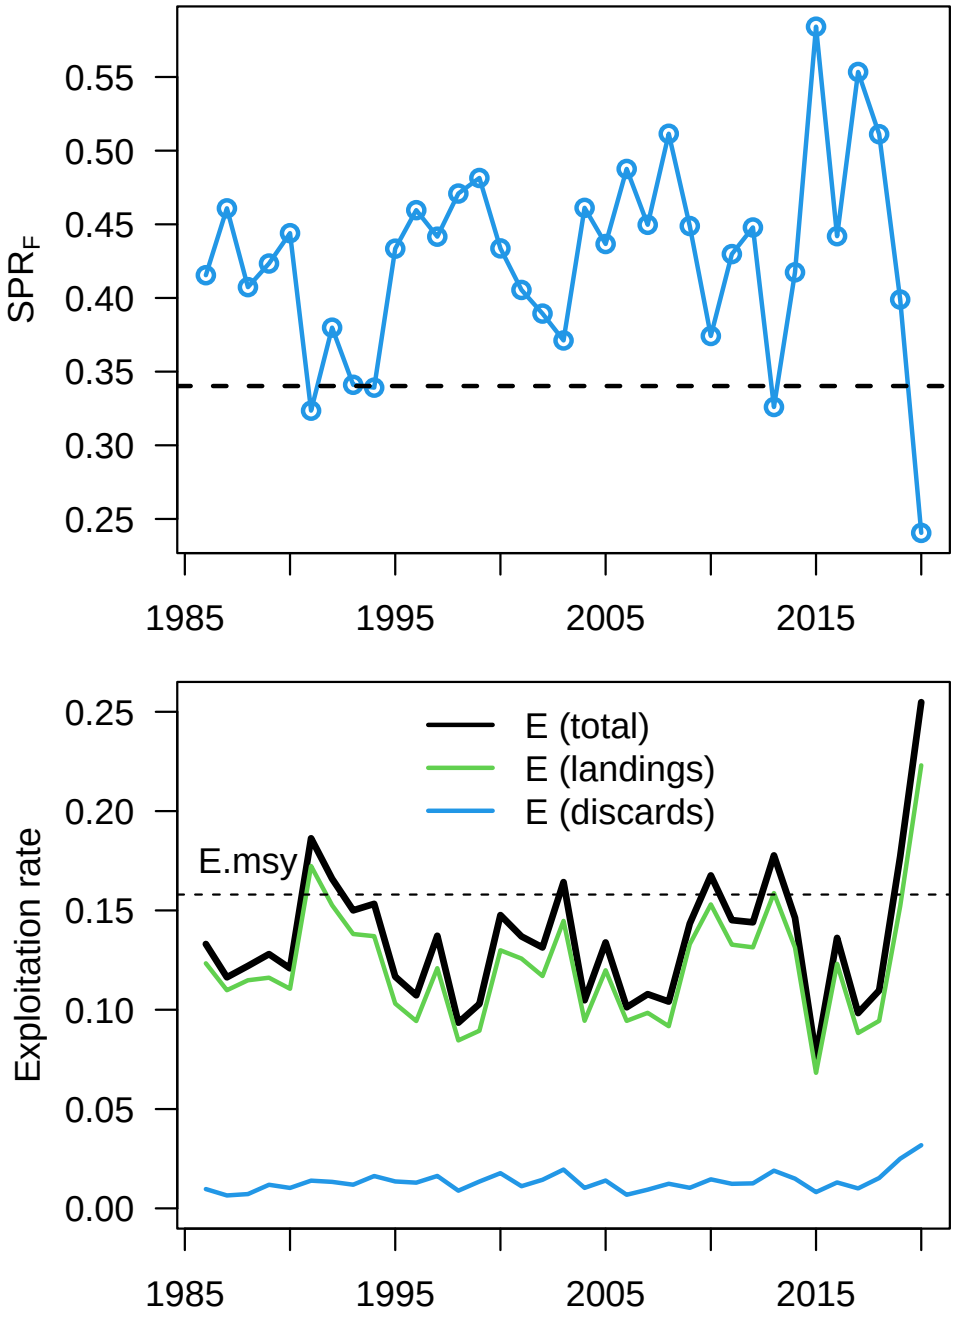

Figure 27. Estimated landings in numbers by fishery from the catch-age model. cH refers to commercial handline, cP to commercial pound net, cG to commercial gill net, cC to commercial cast net, and GR for recreational.

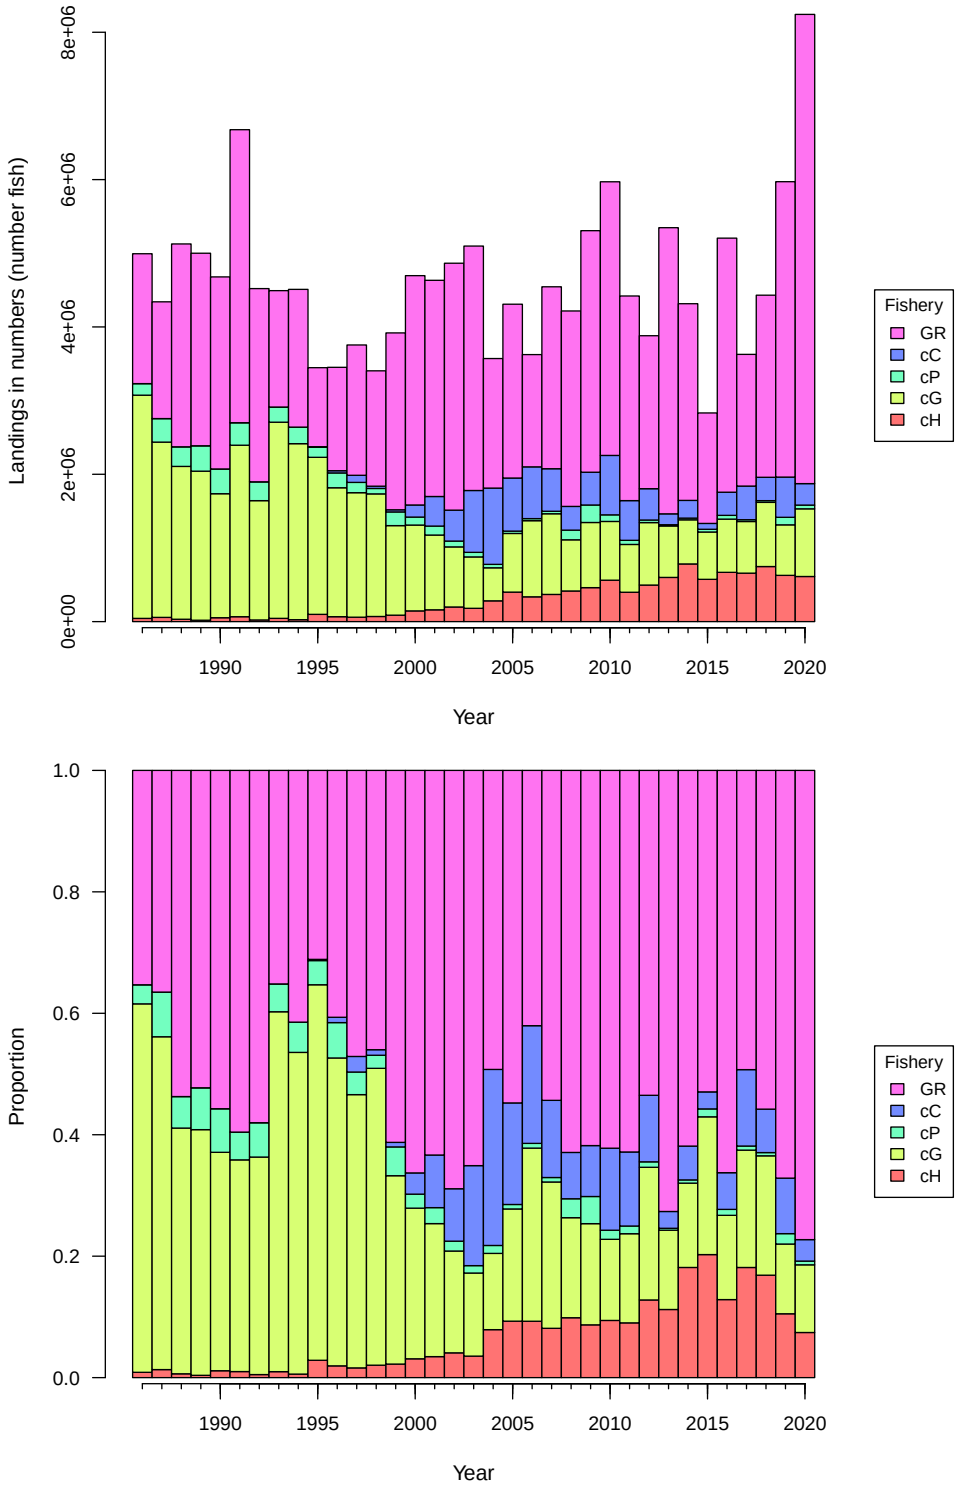

Figure 28. Estimated landings in whole weight by fishery from the catch-age model. cH refers to commercial hand-line, cP to commercial pound net, cG to commercial gill net, cC to commercial cast net, and GR for recreational. Horizontal dashed line in the top panel corresponds to the point estimate of MSY.

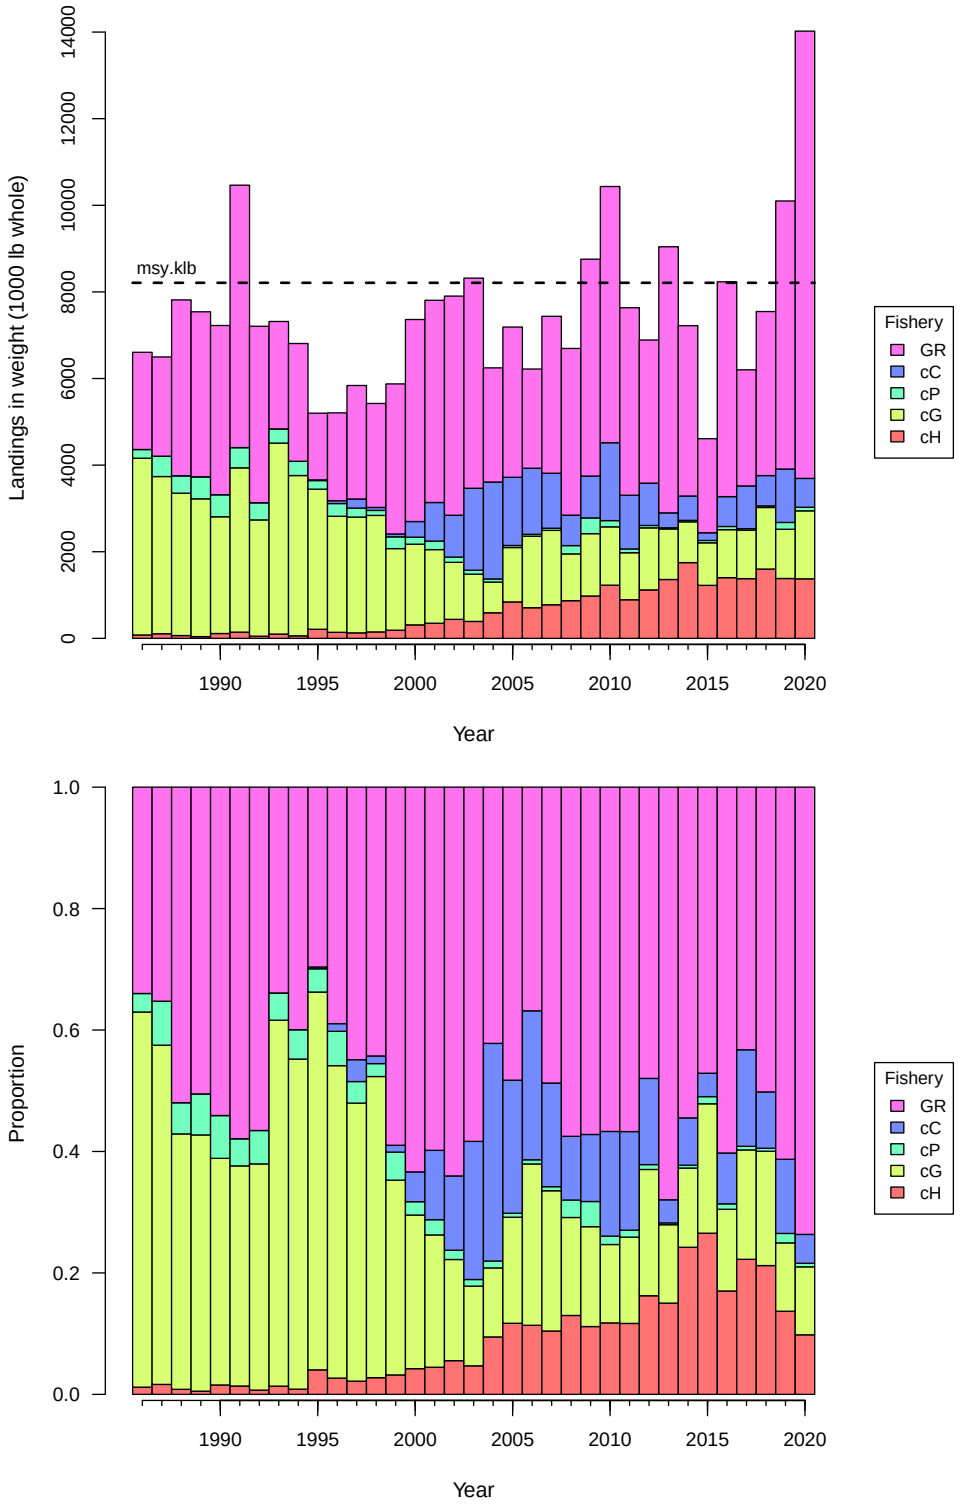

Figure 29. Estimated discards in numbers by fishery from the catch-age model. SB refers to shrimp bycatch, and GR for recreational.

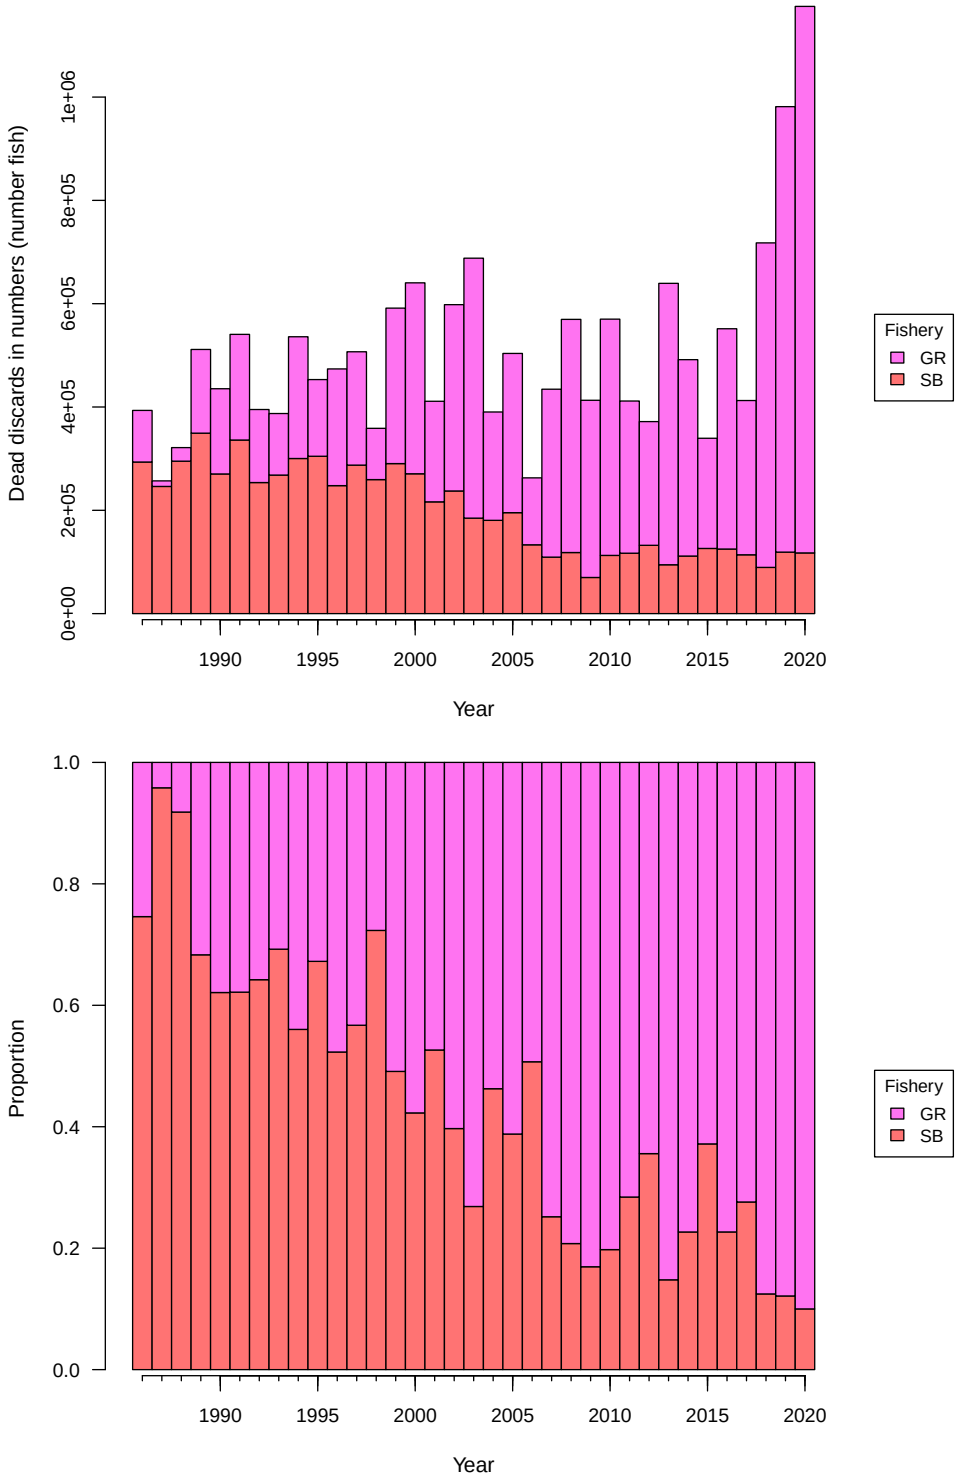

Figure 30. Estimated discards in whole weight by fishery from the catch-age model. SB refers to shrimp bycatch, and GR for recreational.

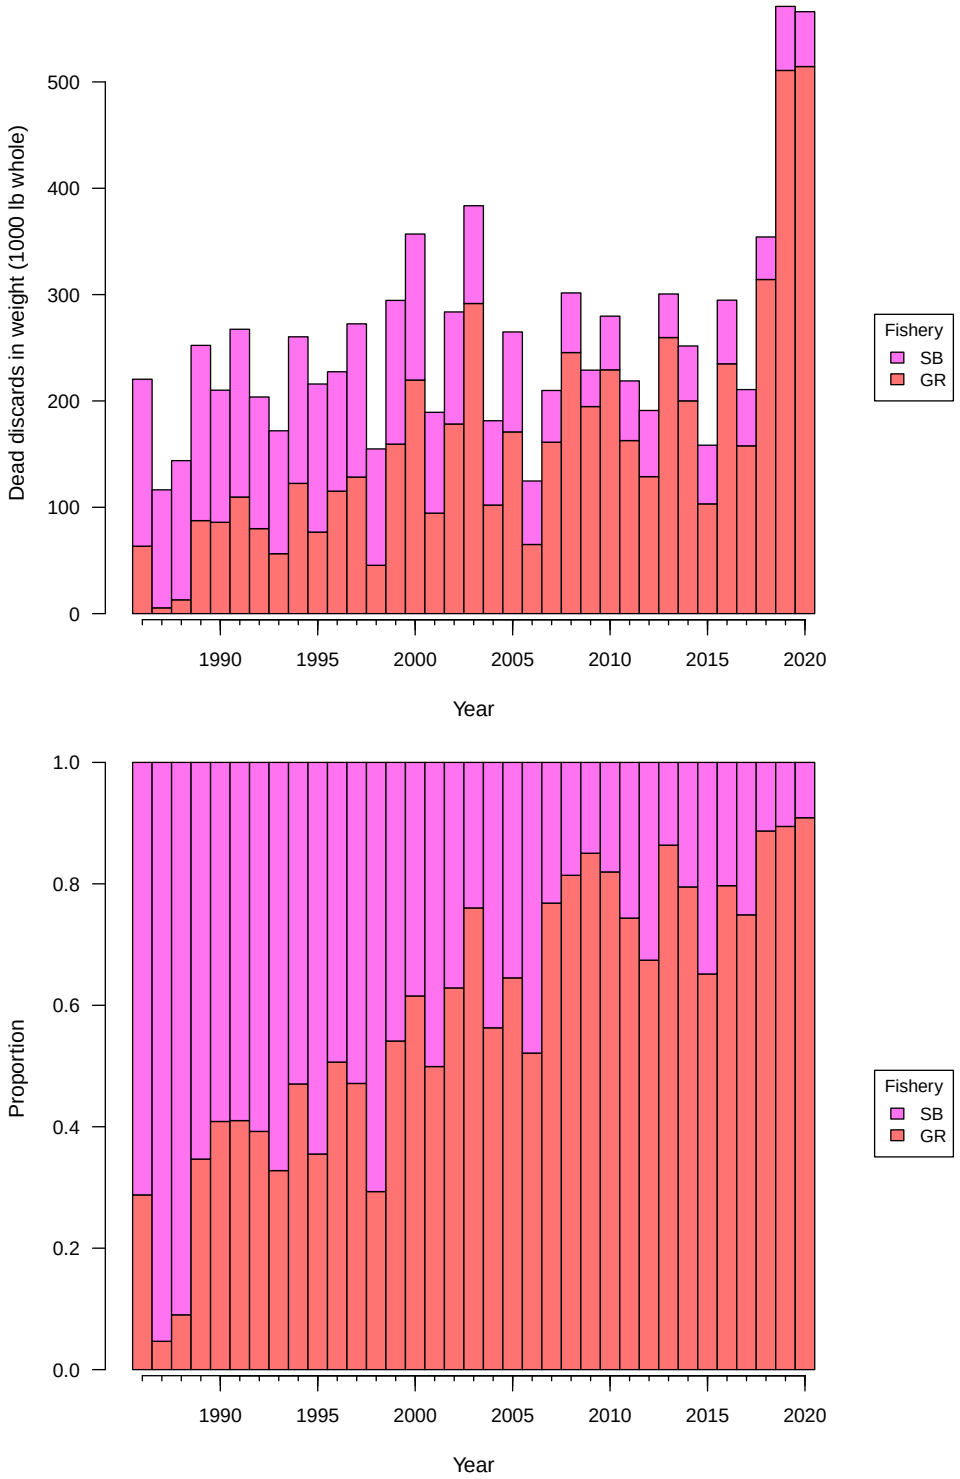

Figure 31. Top panel: Beverton–Holt spawner-recruit curves, with and without lognormal bias correction. The expected (upper) curve was used for computing management benchmarks. Years within panel indicate year of recruitment generated from spawning biomass one year prior. Bottom panel: log of recruits (number age-0 fish) per spawner (mature female gonad weight) as a function of spawners.

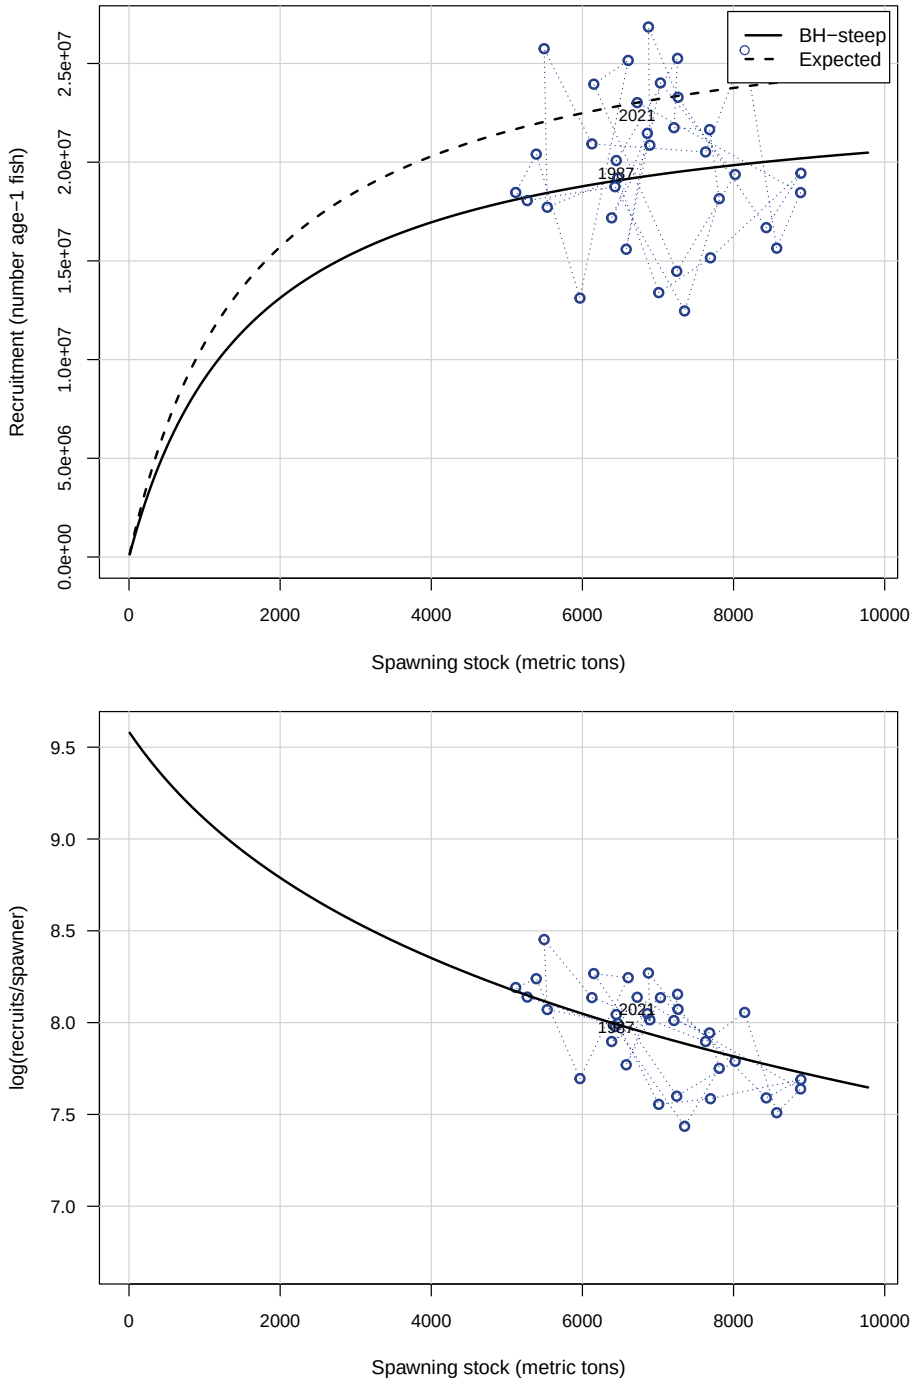

Figure 32. Probability densities of spawner-recruit quantities: Mean recruits (R0, age-0 fish), median recruits, and unfished spawners per recruit. Solid vertical lines represent point estimates or values from the base run of the Beaufort Assessment Model; dashed vertical lines represent medians from the MCBE runs.

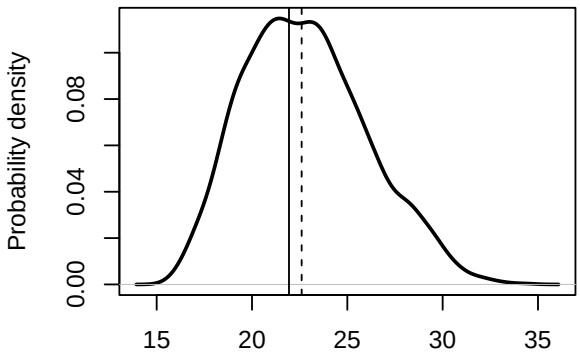

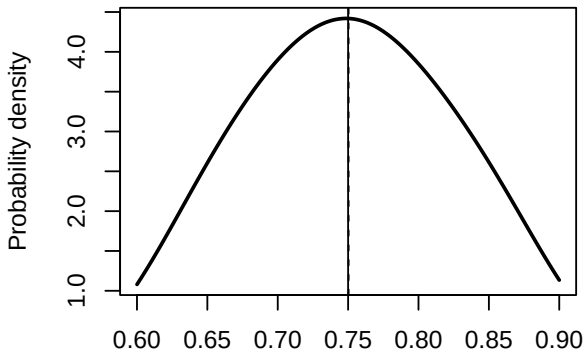

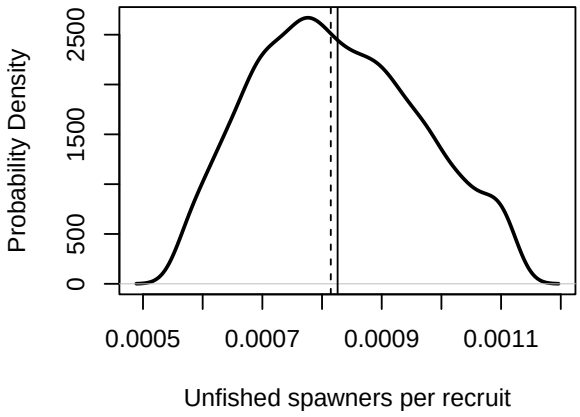

Figure 33. Top panel: yield per recruit. Bottom panel: spawning potential ratio (spawning biomass per recruit relative to that at the unfished level), from which the y% levels provide $F_{y\%}$. Current F (Fcur) is the geometric mean full F from the last 3 years of the assessment. Both curves are based on average selectivity from the end of the assessment period.

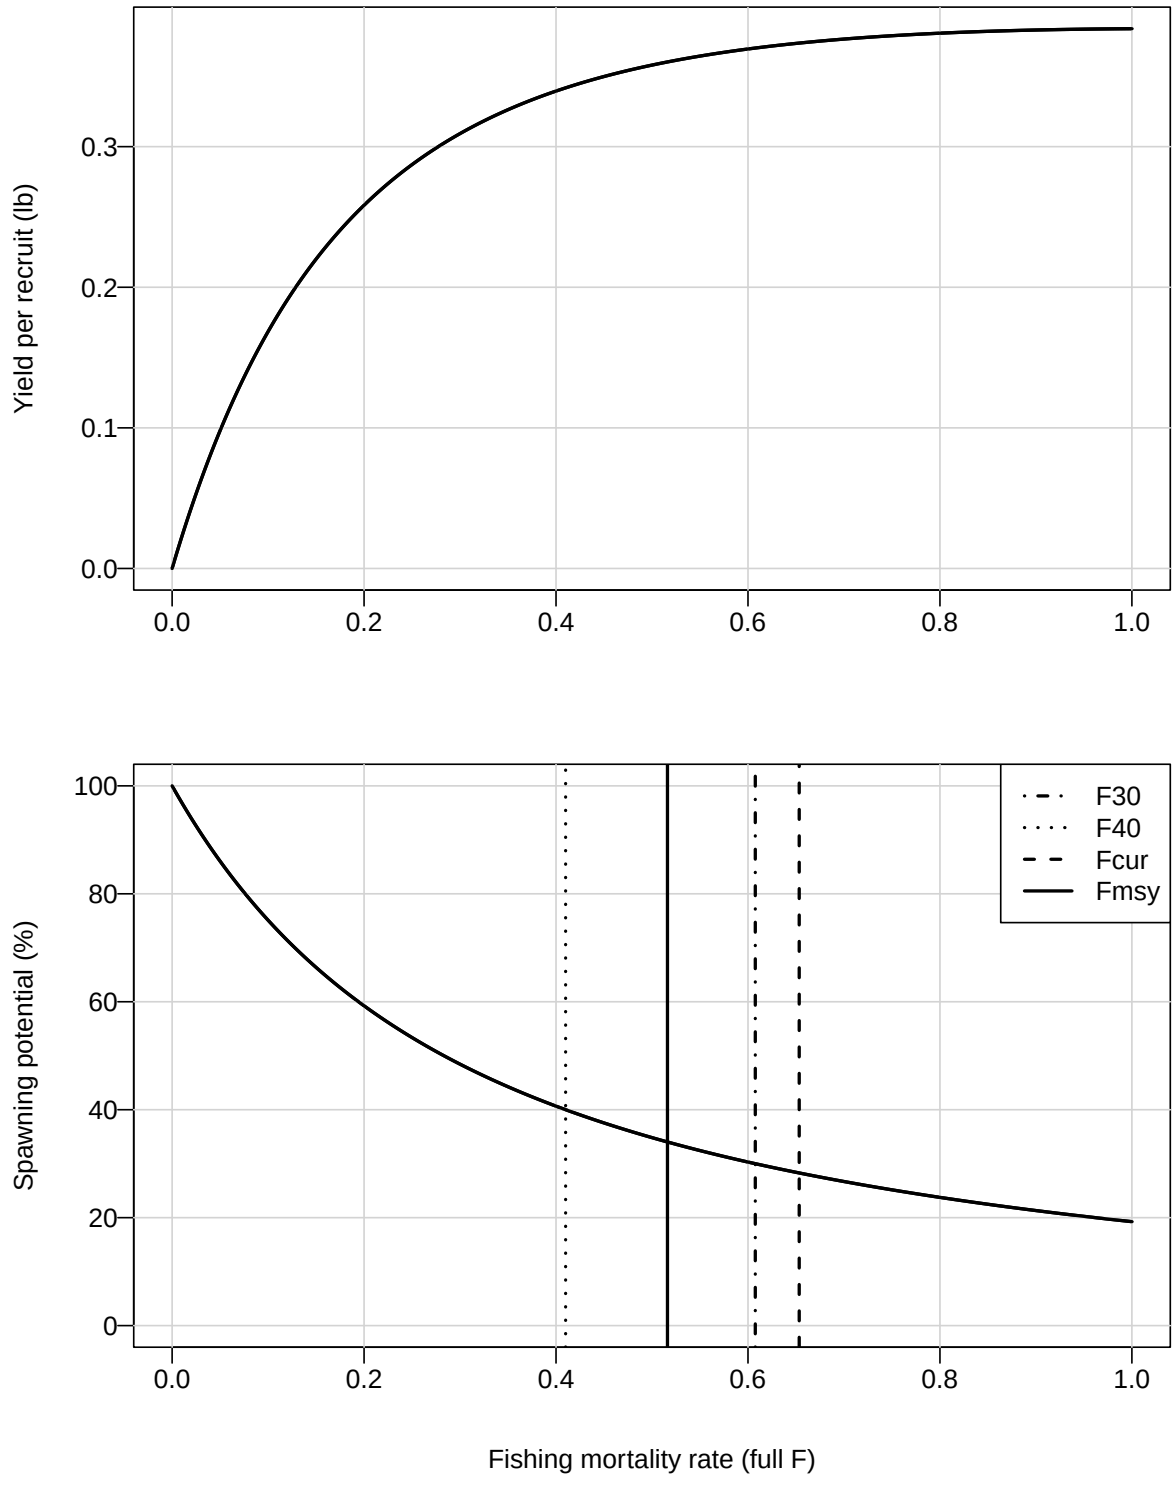

Figure 34. Top panel: equilibrium landings. The peak occurs where fishing rate is $F_{\mathrm{MSY}} = 0.52$ *and equilibrium landings are* MSY = 8210.19 *(1000 lb). Bottom panel: equilibrium spawning biomass. Both curves are based on average selectivity from the end of the assessment period.*

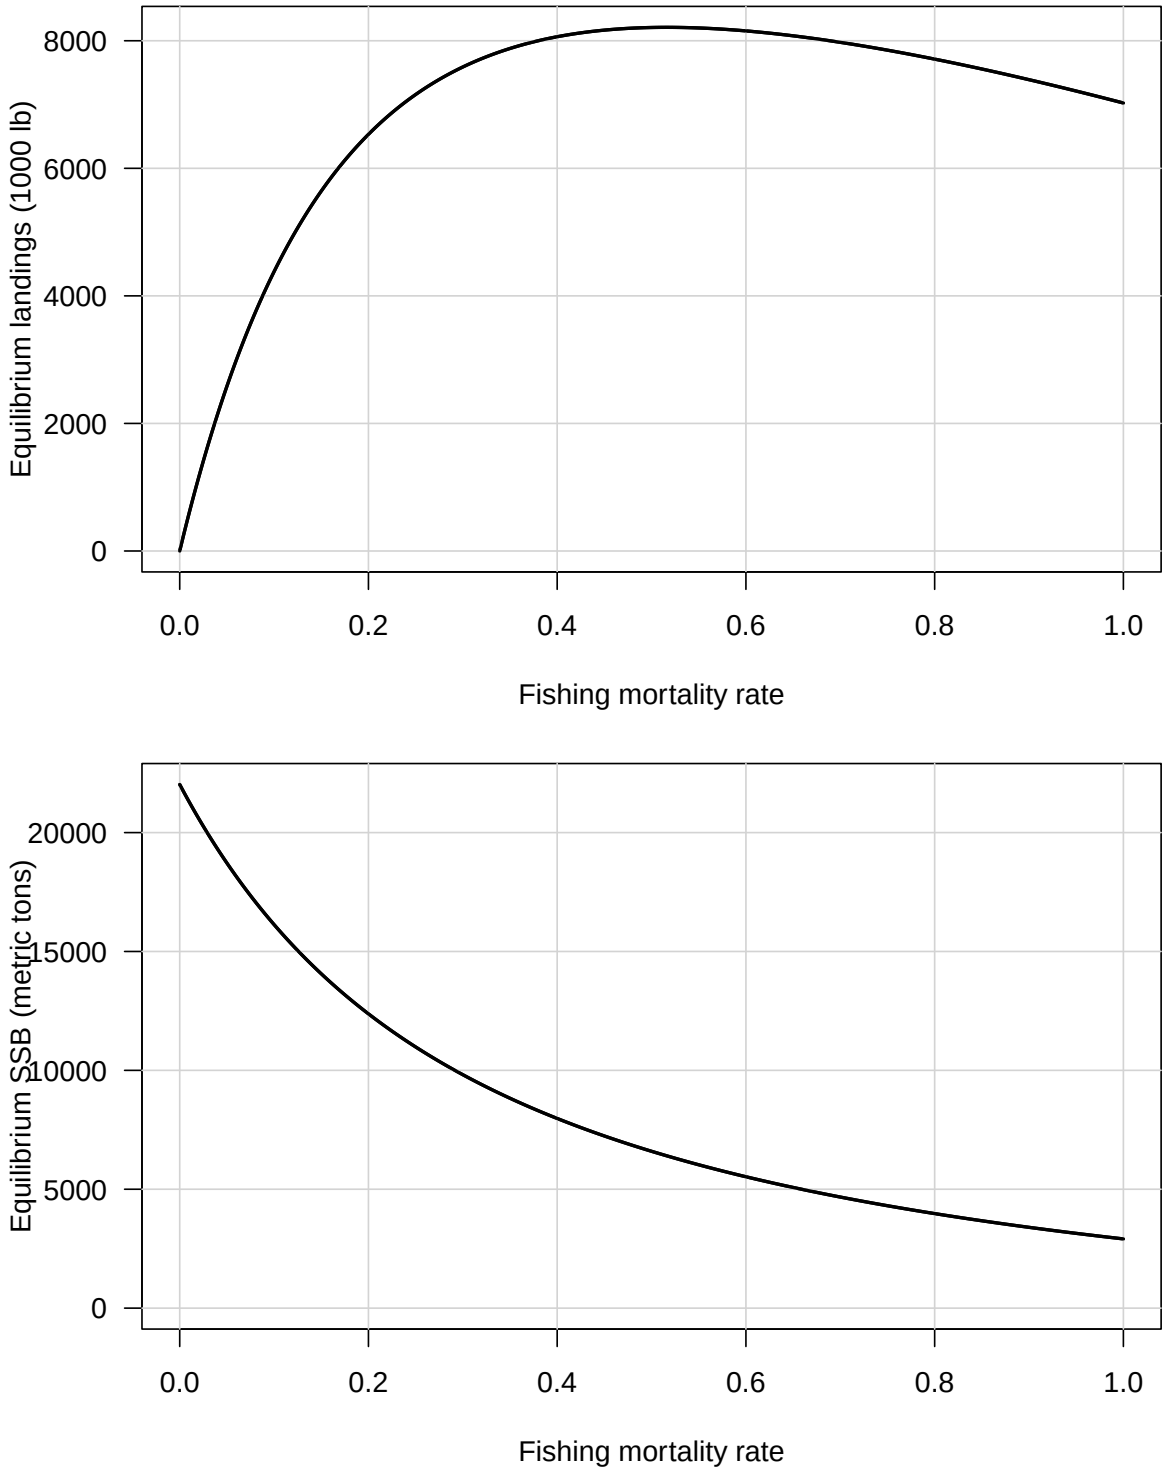

Figure 35. Equilibrium landings as a function of equilibrium biomass, which itself is a function of fishing mortality rate. The peak occurs where equilibrium biomass is $B_{\mathrm{MSY}} = 19588.3$ *mt and equilibrium landings are* $\mathrm{MSY} = 8210.19$ *(1000 lb).*

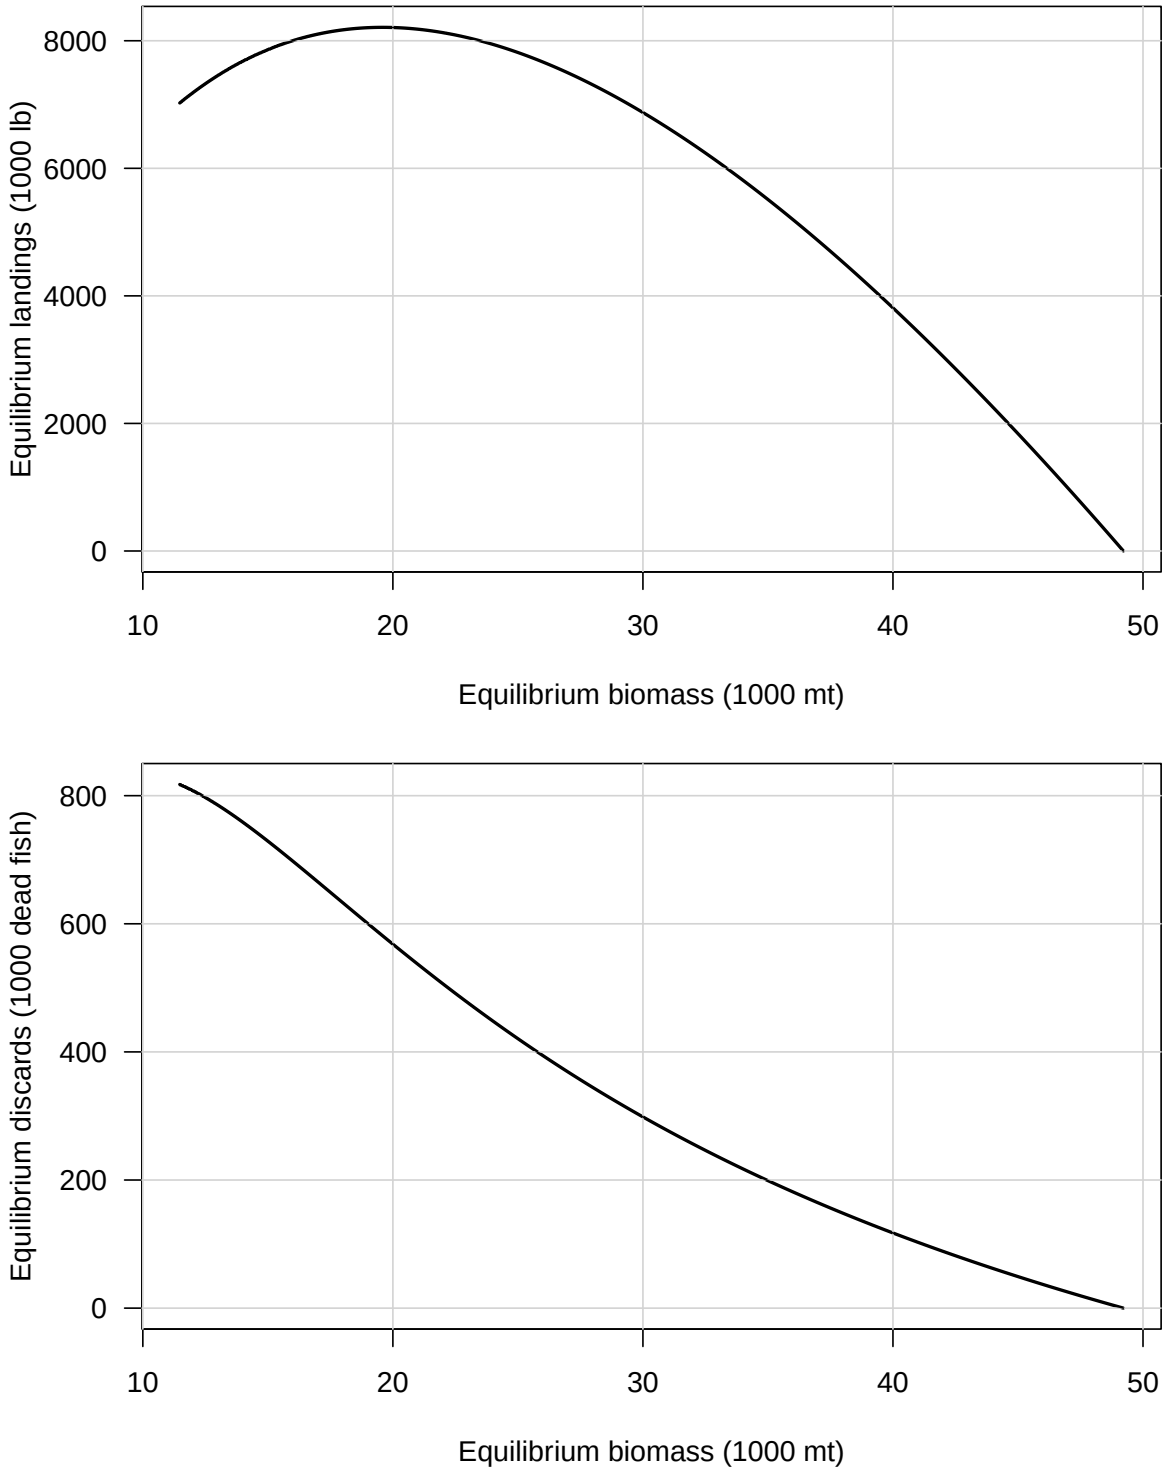

Figure 36. Probability densities of F_{MSY}-related benchmarks from MCB analysis of the Beaufort Assessment Model. Solid vertical line represent point estimates from the base run and the dashed vertical line represent the median of the MCB distribution.

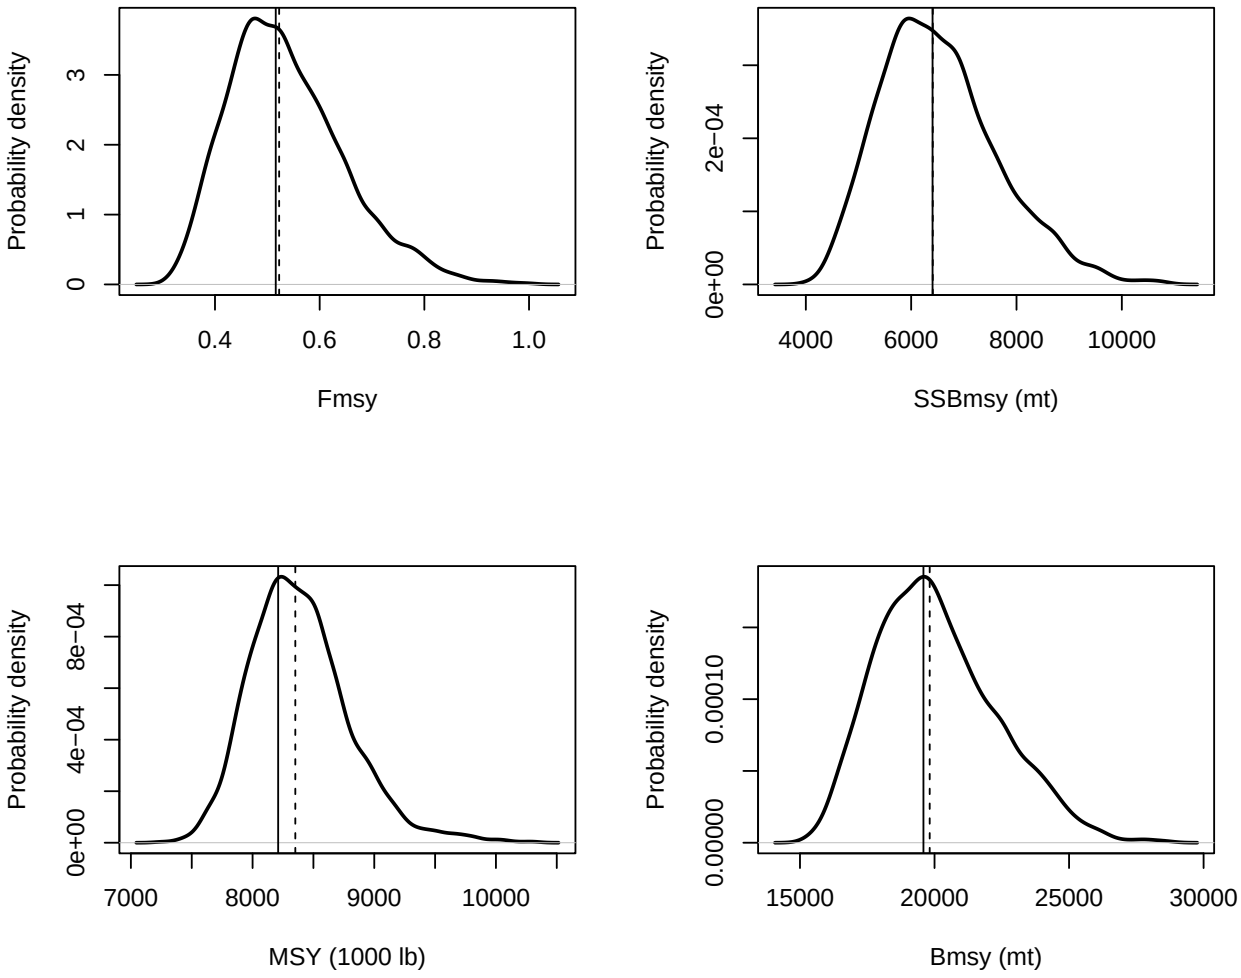

Figure 37. Estimated time series relative to benchmarks. Solid line indicates estimates from base run of the Beaufort Assessment Model; dashed lines indicate the median of the MCB trials; gray error bands indicate 5^{th} *and* 95^{th} *percentiles of the MCB trials. Top panel: spawning biomass relative to the spawning stock biomass at* MSY*. Bottom panel: F relative to* F_{MSY}*.*

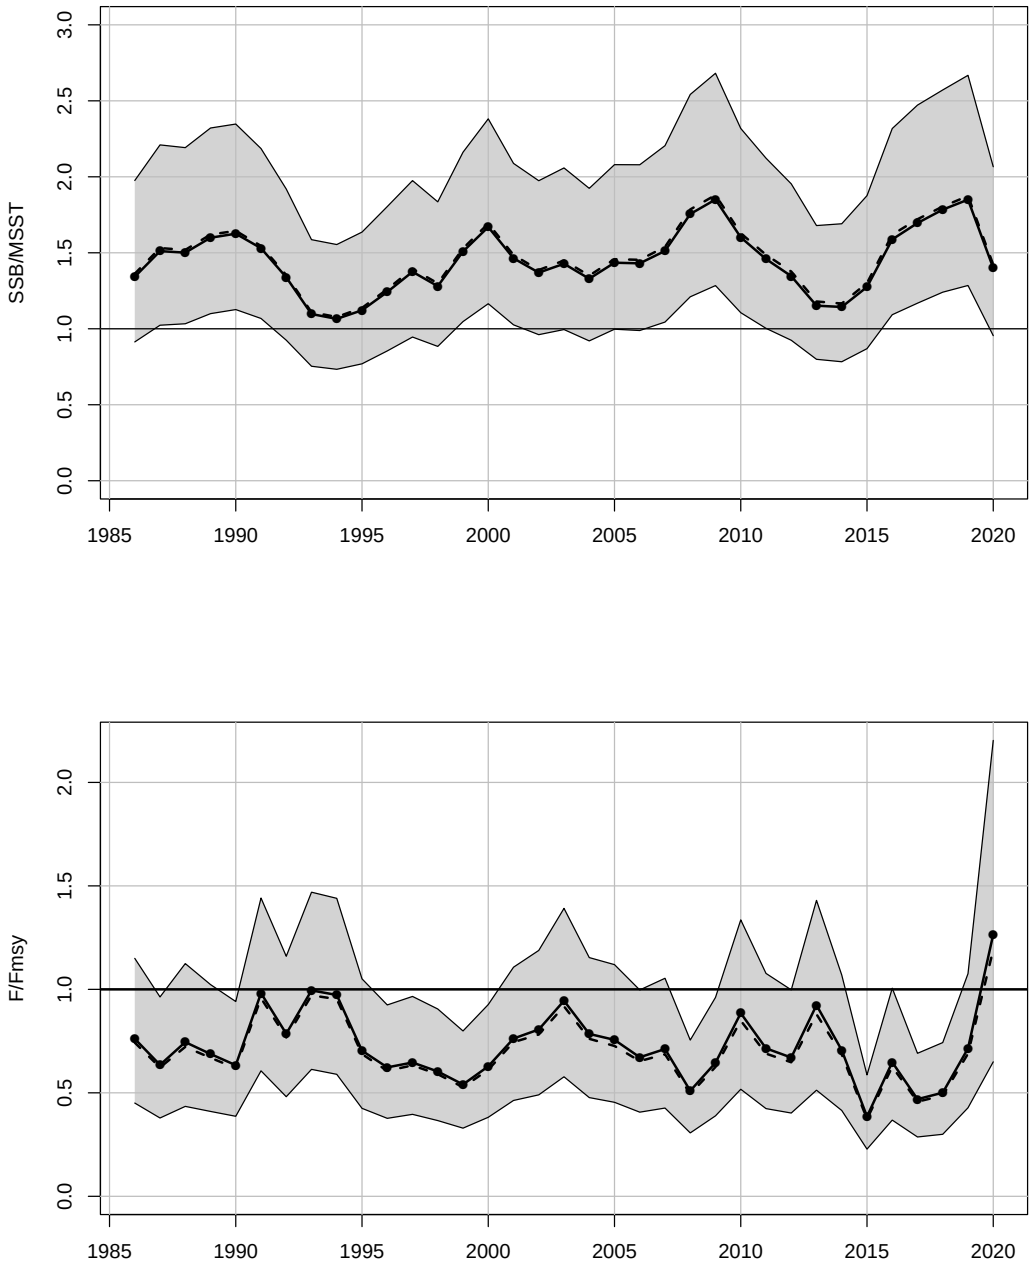

Figure 38. Phase plot of terminal status estimates from MCB analysis of the Beaufort Assessment Model. The intersection of crosshairs indicates estimates from the base run; lengths of crosshairs defined by 5^{th} and 95^{th} percentiles.

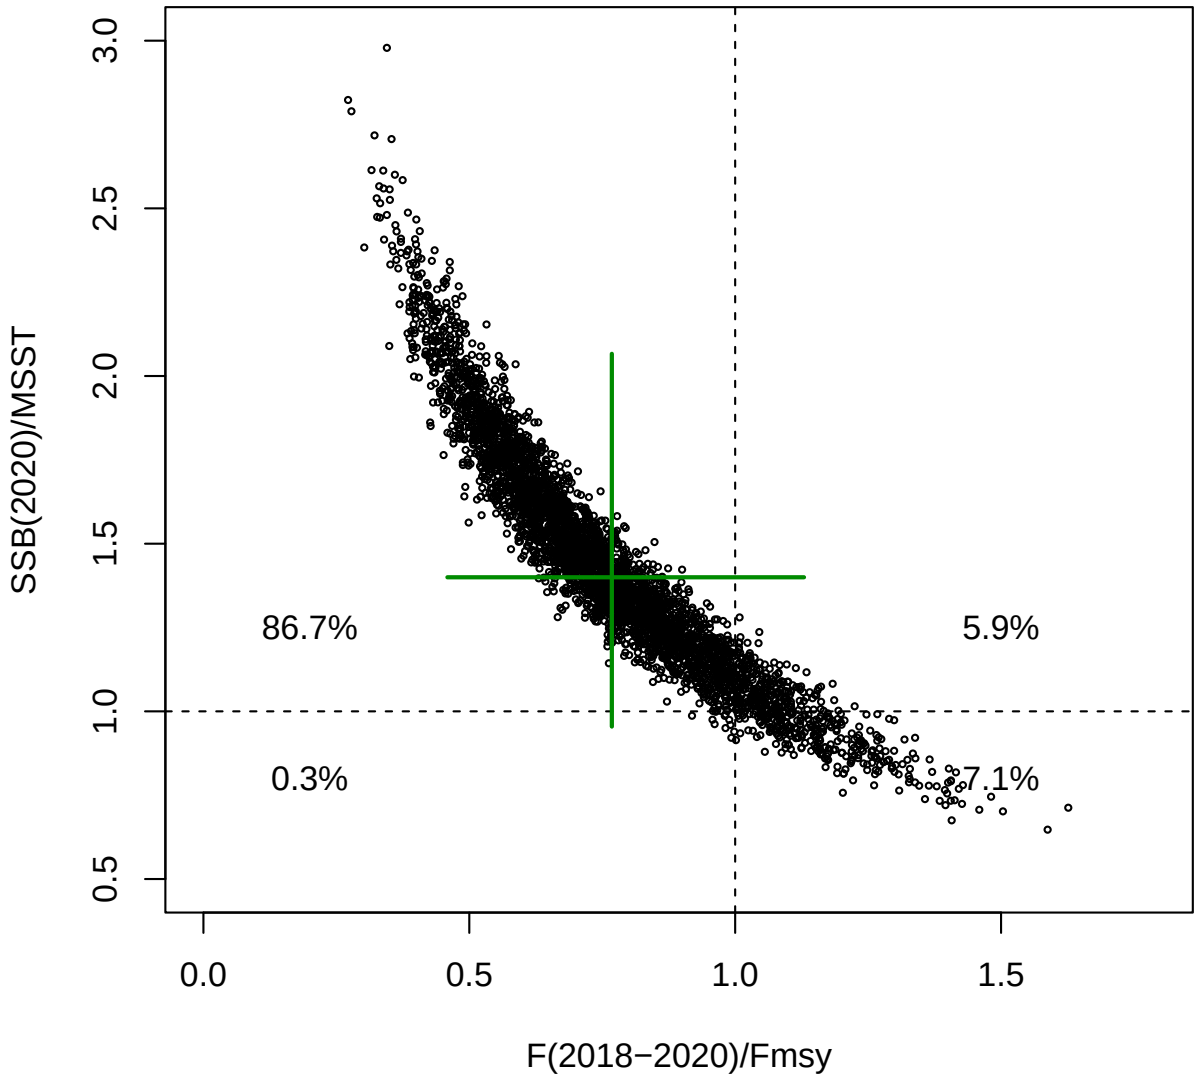

Figure 39. Phase plot of terminal status estimates from MCB analysis of the Beaufort Assessment Model. The intersection of crosshairs indicates estimates from the base run; lengths of crosshairs defined by 5^{th} and 95^{th} percentiles.

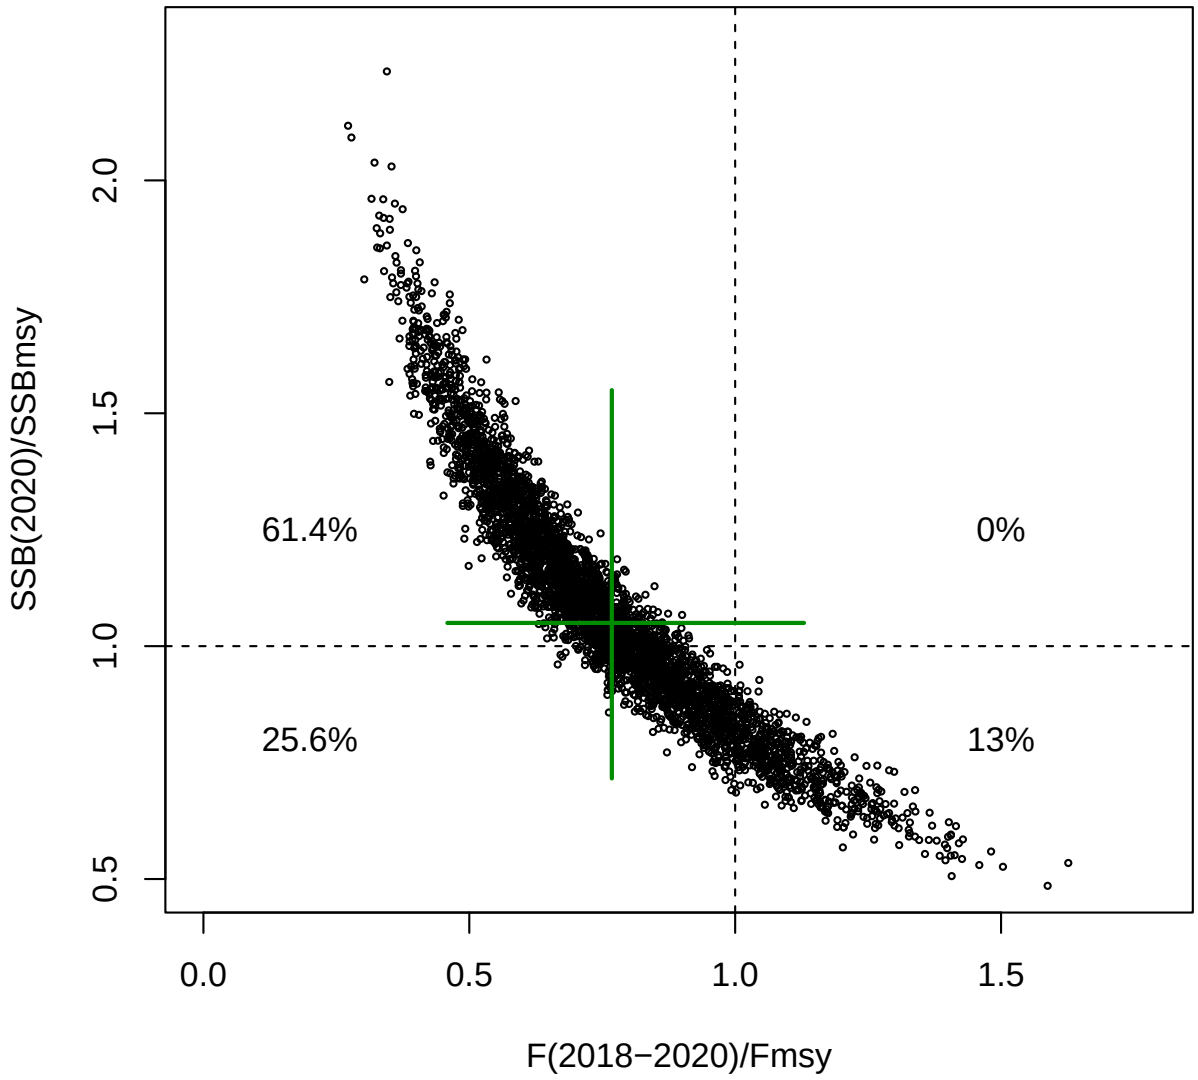

Figure 40. Probability densities of terminal status estimates from MCB analysis of the Beaufort Assessment Model. Solid vertical lines represent point estimates from the base run and dashed vertical lines indicated the median of MCB trials.

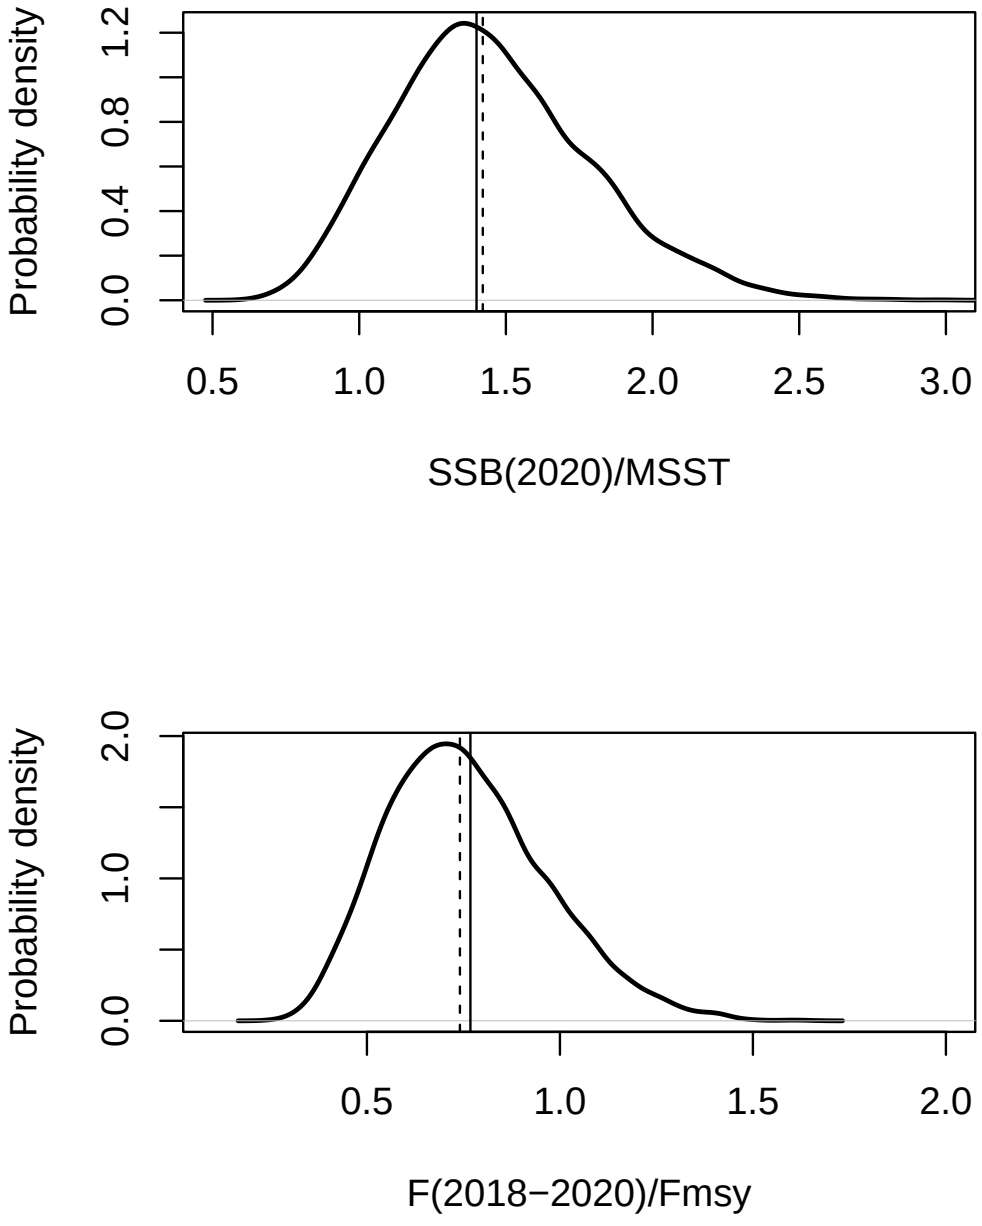

Figure 41. Comparison between SEDAR-28 and SEDAR-78 status indicators. Top panel: Apical F relative to F_{MSY}. *Bottom panel: spawning biomass relative to* MSST.

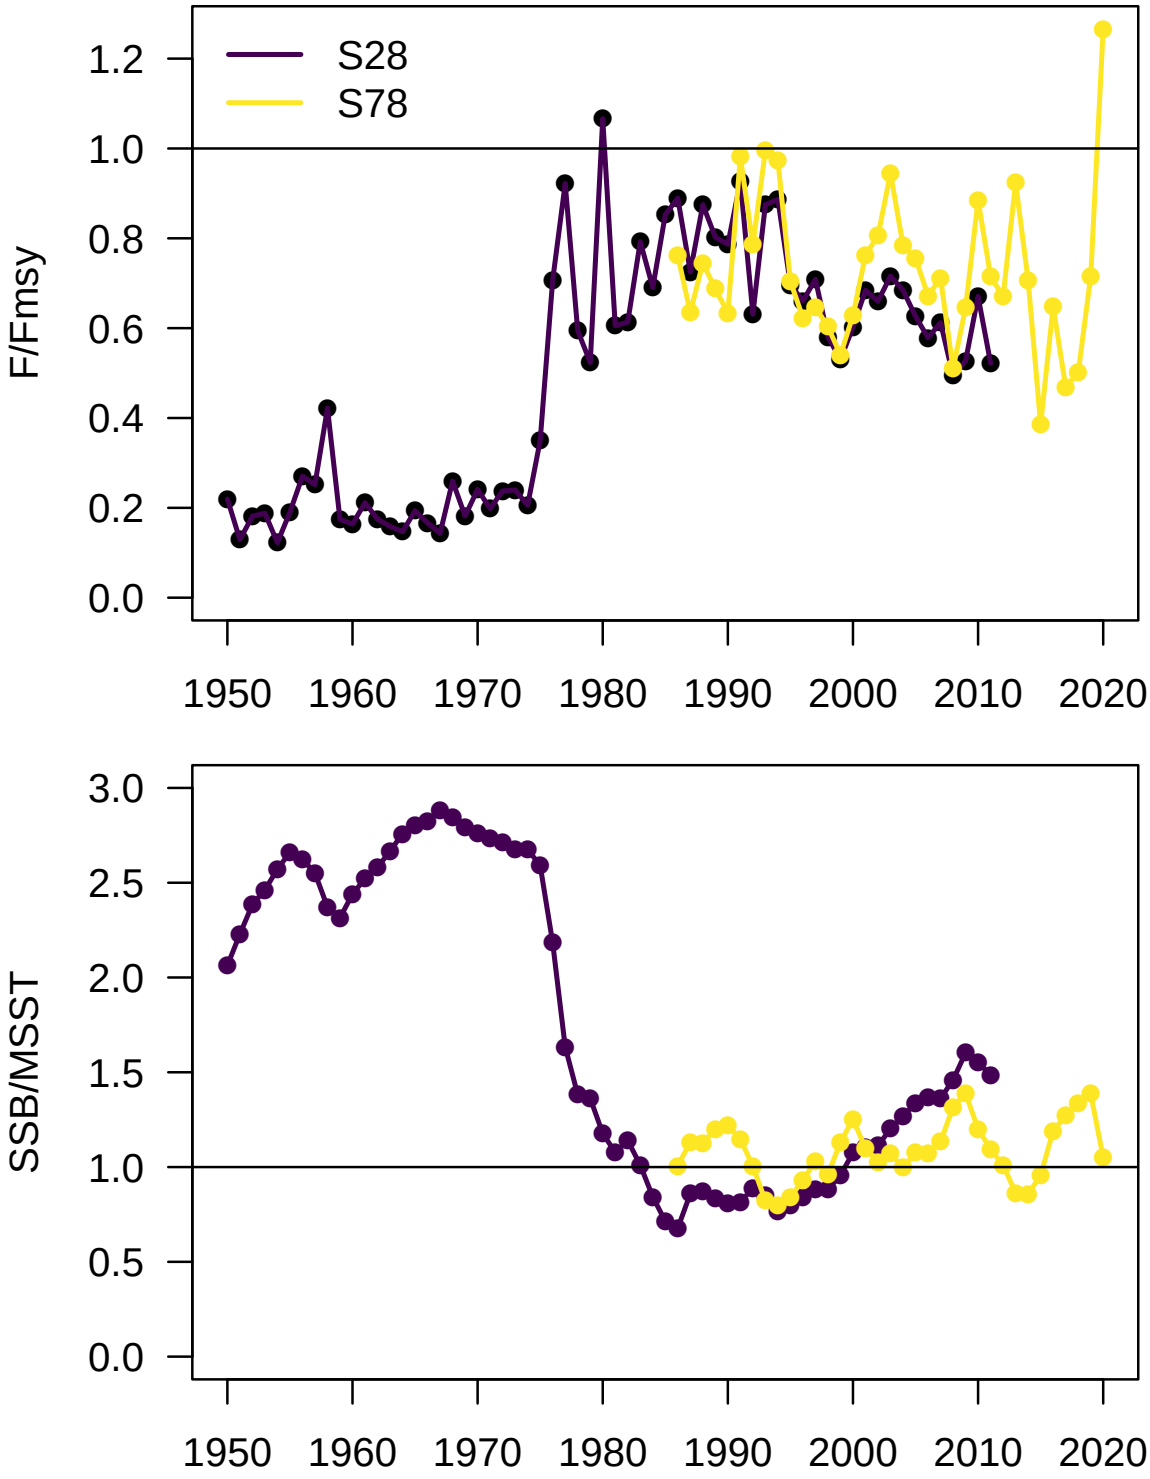

Figure 42. Spanish mackerel: Sensitivity of results to dropping the commercial handline (cH) index. (sensitivity run S1). Top panel – Ratio of F to F_{MSY}. Bottom panel – Ratio of SSB *to* SSB_{MSY}.

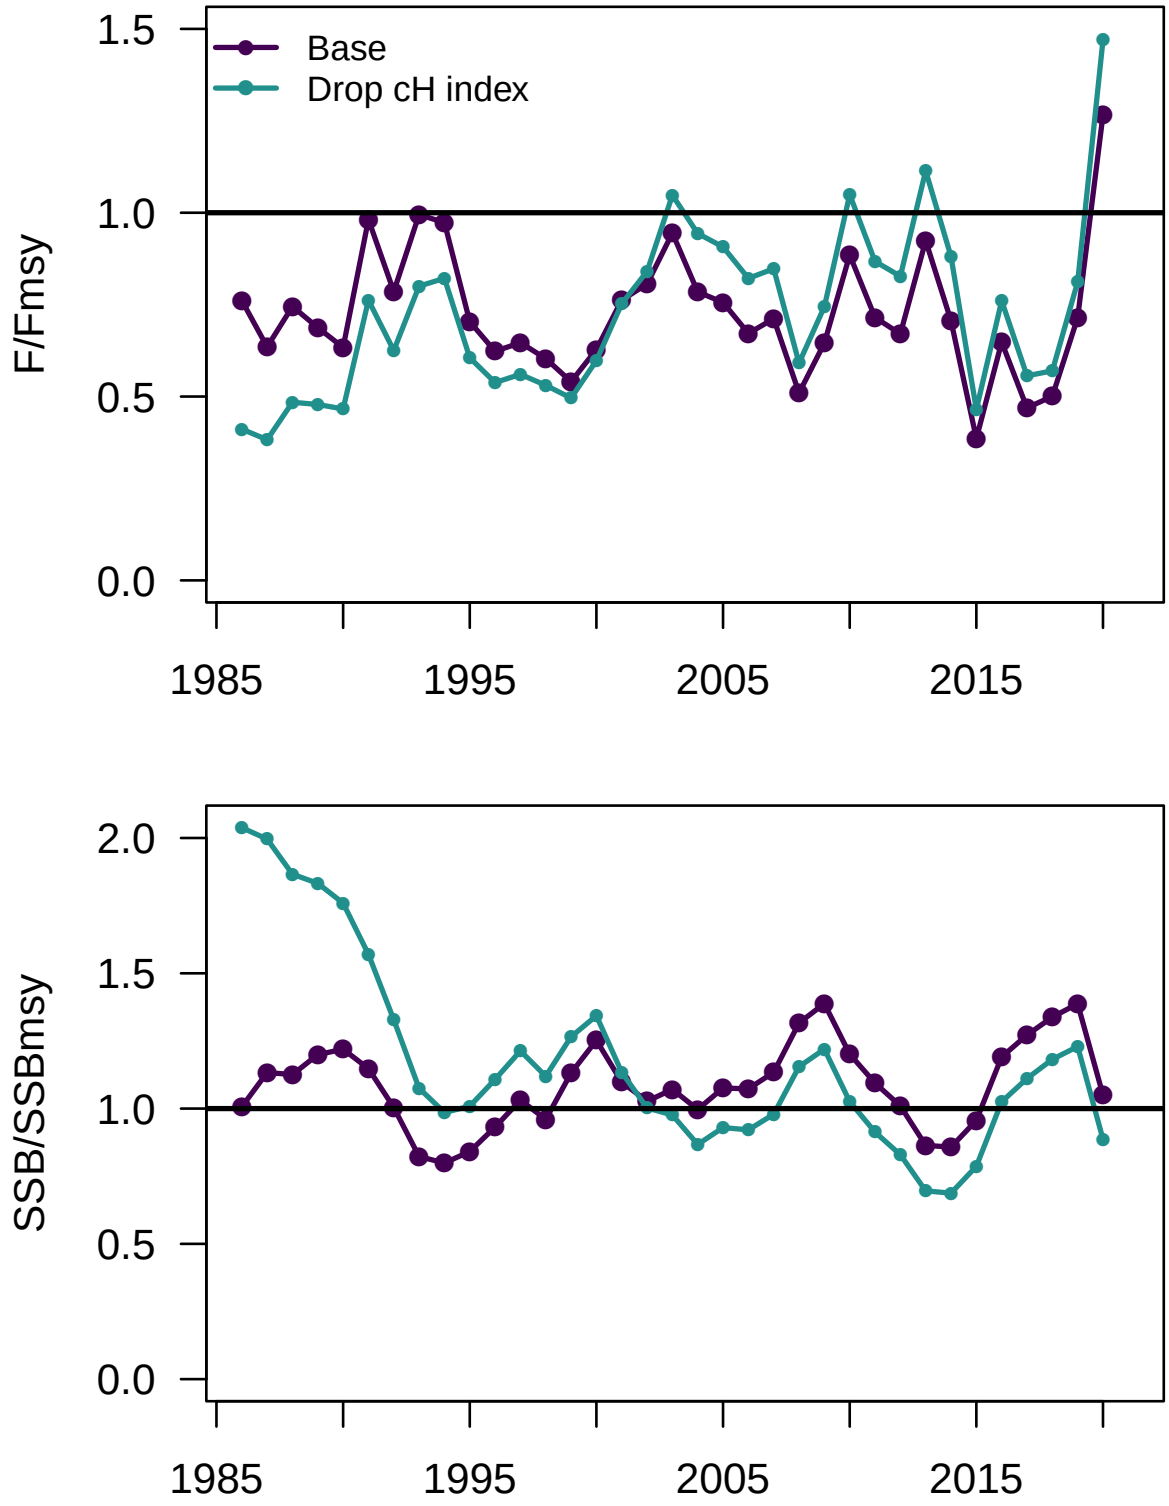

Figure 43. Spanish mackerel: Sensitivity of results to estimates of natural mortality M. (sensitivity runs S2 and S3). Top panel – Ratio of F to F_{MSY}. Bottom panel – Ratio of SSB *to* SSB_{MSY}.

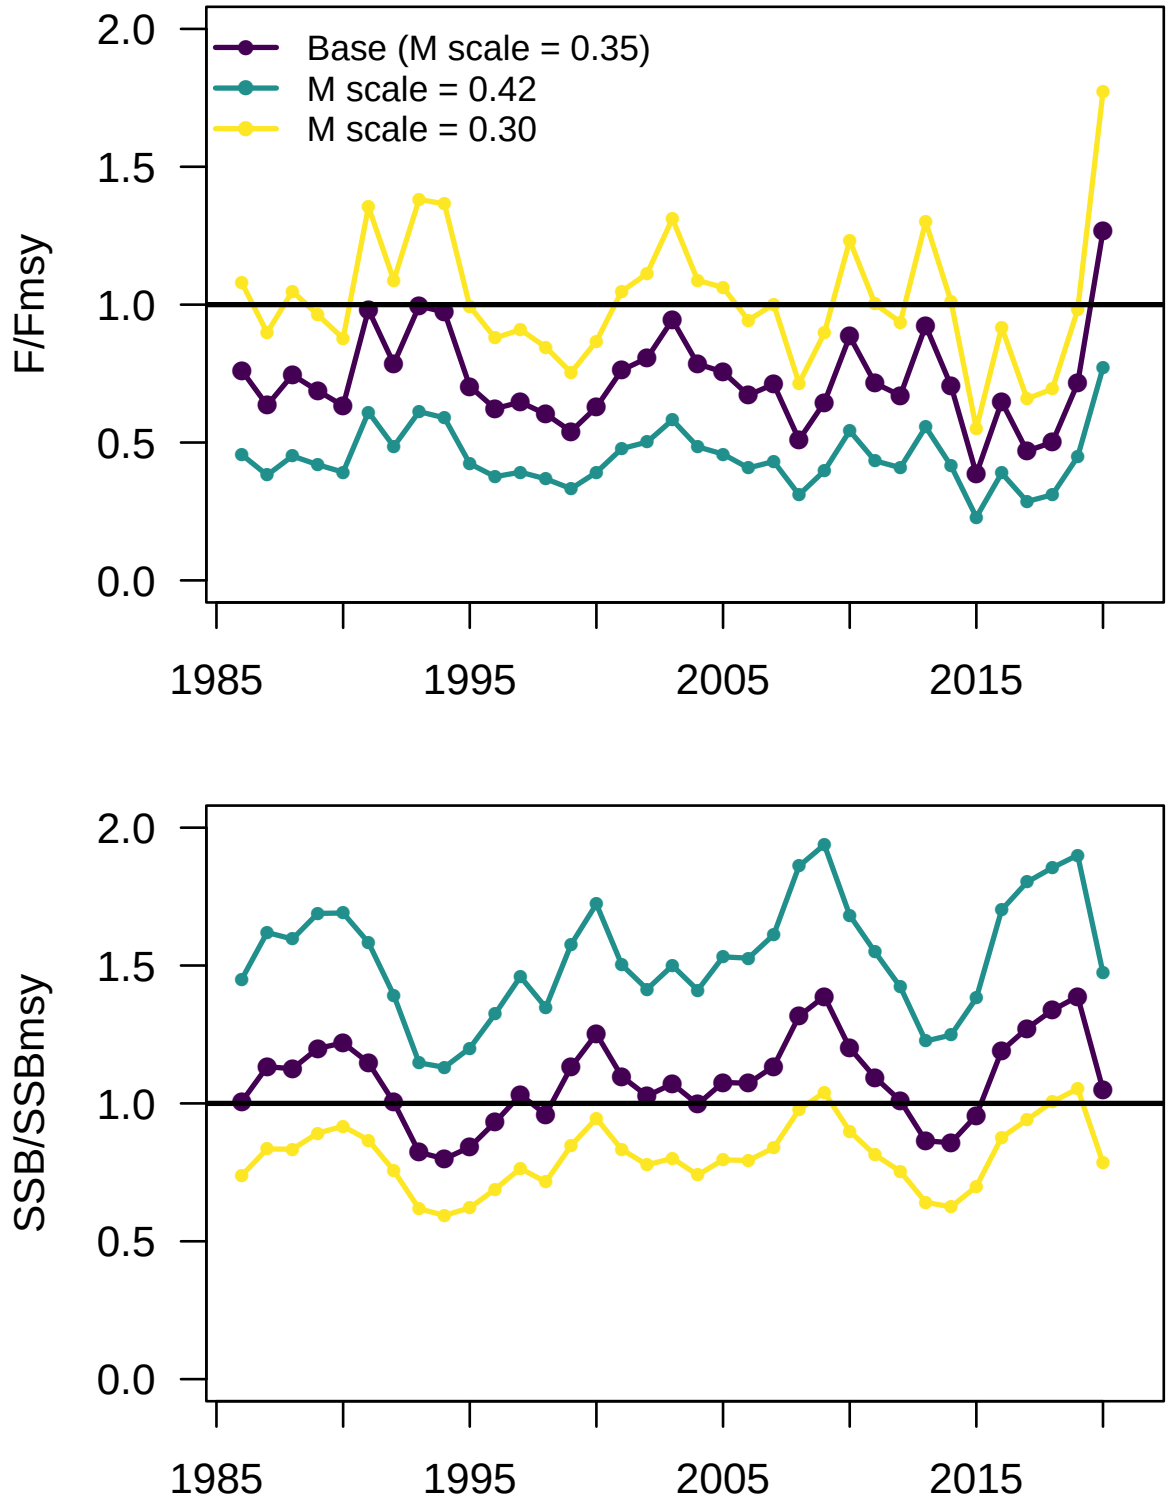

Figure 44. Spanish mackerel: Sensitivity of results to fixed values of steepness (sensitivity runs S4 and S5). Top panel – Ratio of F to F_{MSY}. Bottom panel – Ratio of SSB *to* SSB_{MSY}.

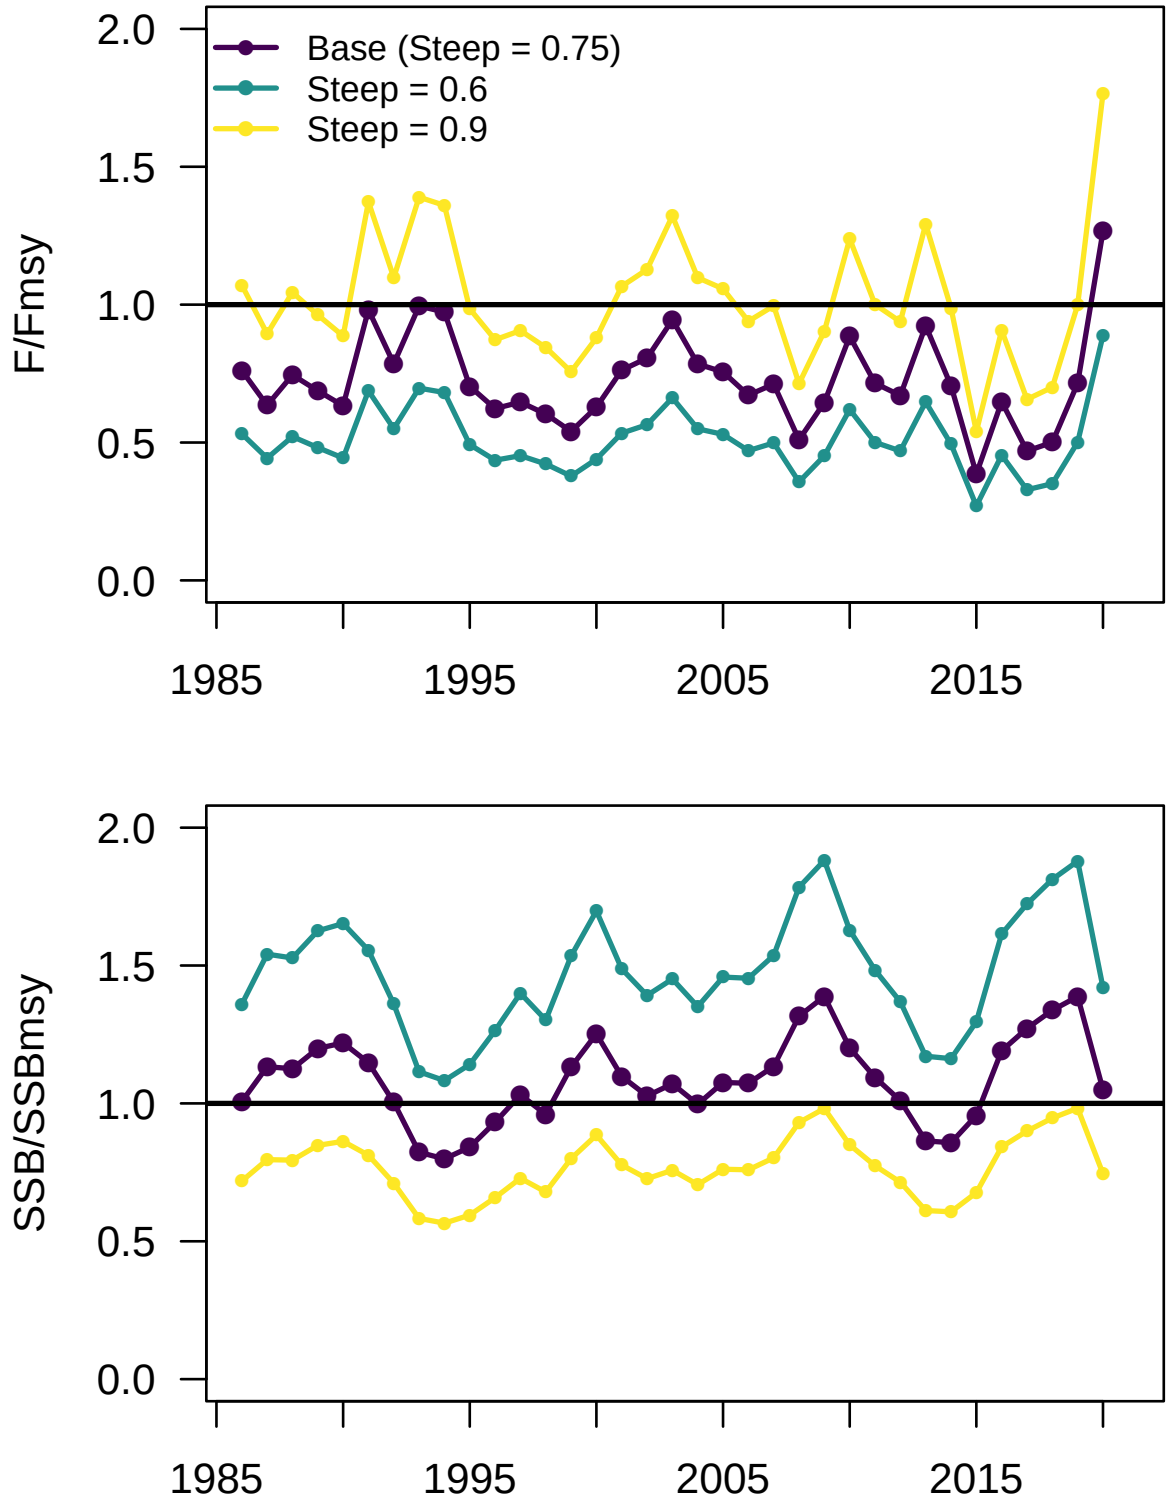

Figure 45. Spanish mackerel: Sensitivity of results to fixed values of general recreational (GR) discard mortality rate. (sensitivity runs S6 and S7). Top panel – Ratio of F to F_{MSY}. Bottom panel – Ratio of SSB *to* SSB_{MSY}.

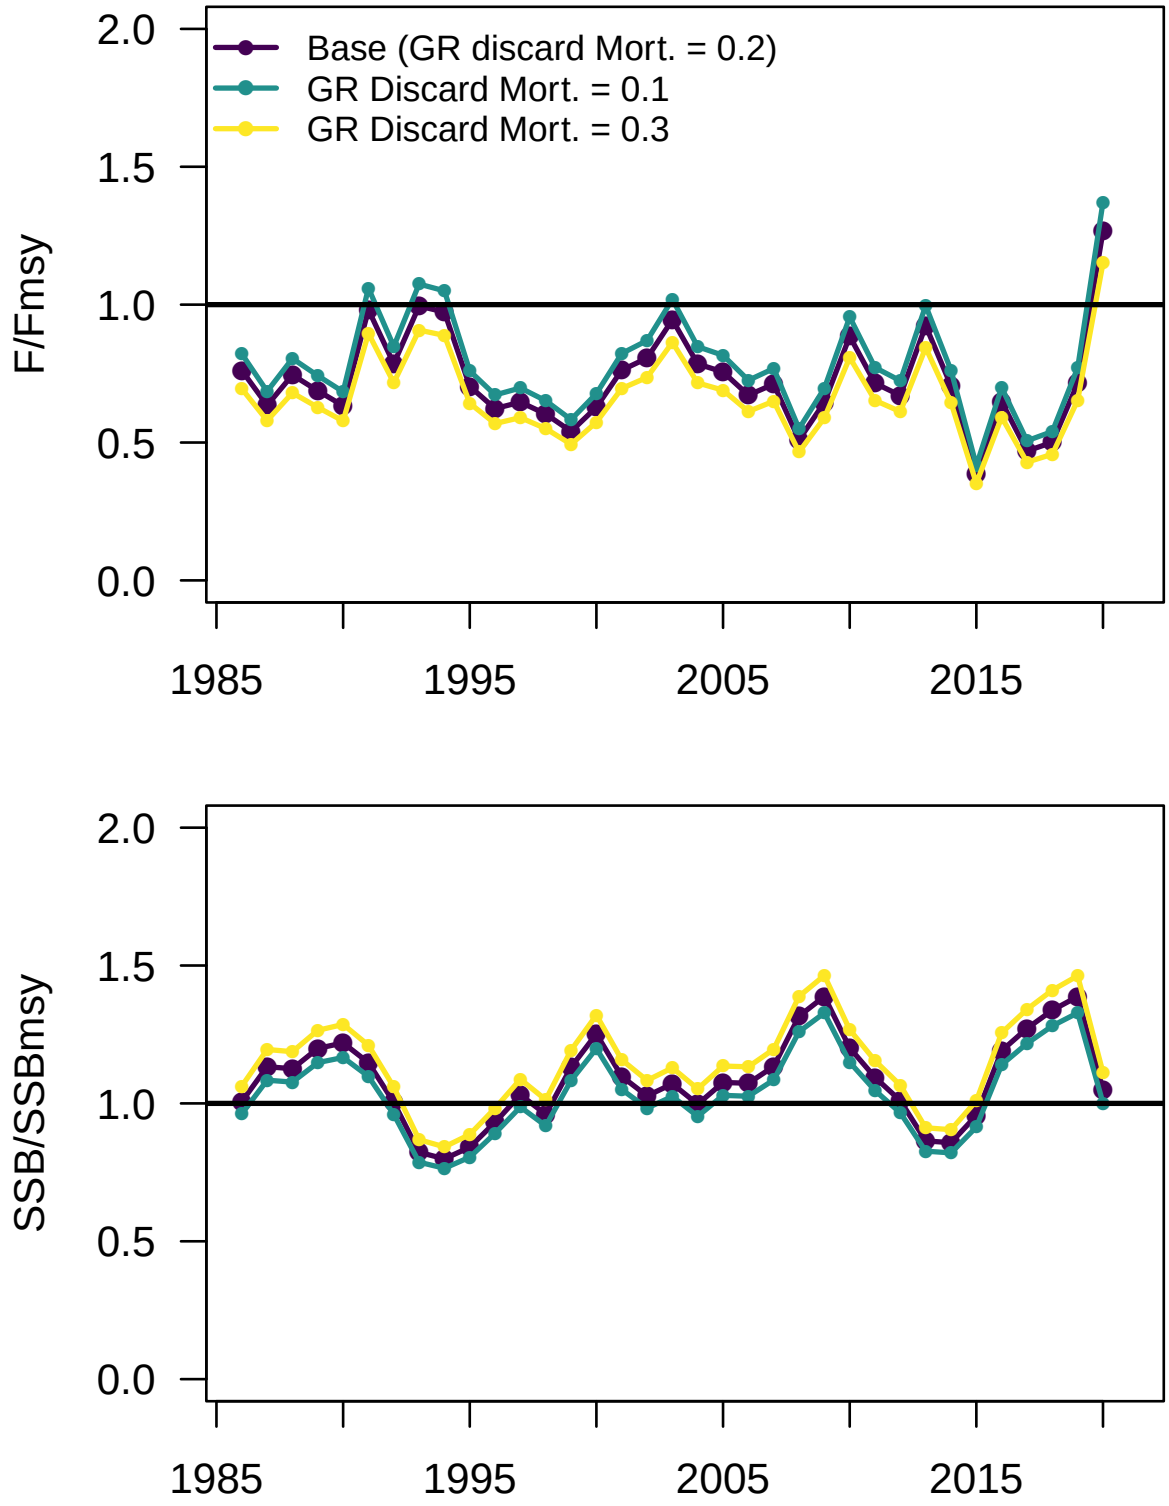

Figure 46. Retrospective analyses. Sensitivity to terminal year of data (sensitivity runs Retro 1–5). Top Panel: Fishing mortality rate, where solid circles show geometric mean of terminal three years, as used to compute fishing status. Middle Panel: Recruitment time series. Bottom Panel: Spawning stock biomass time series.

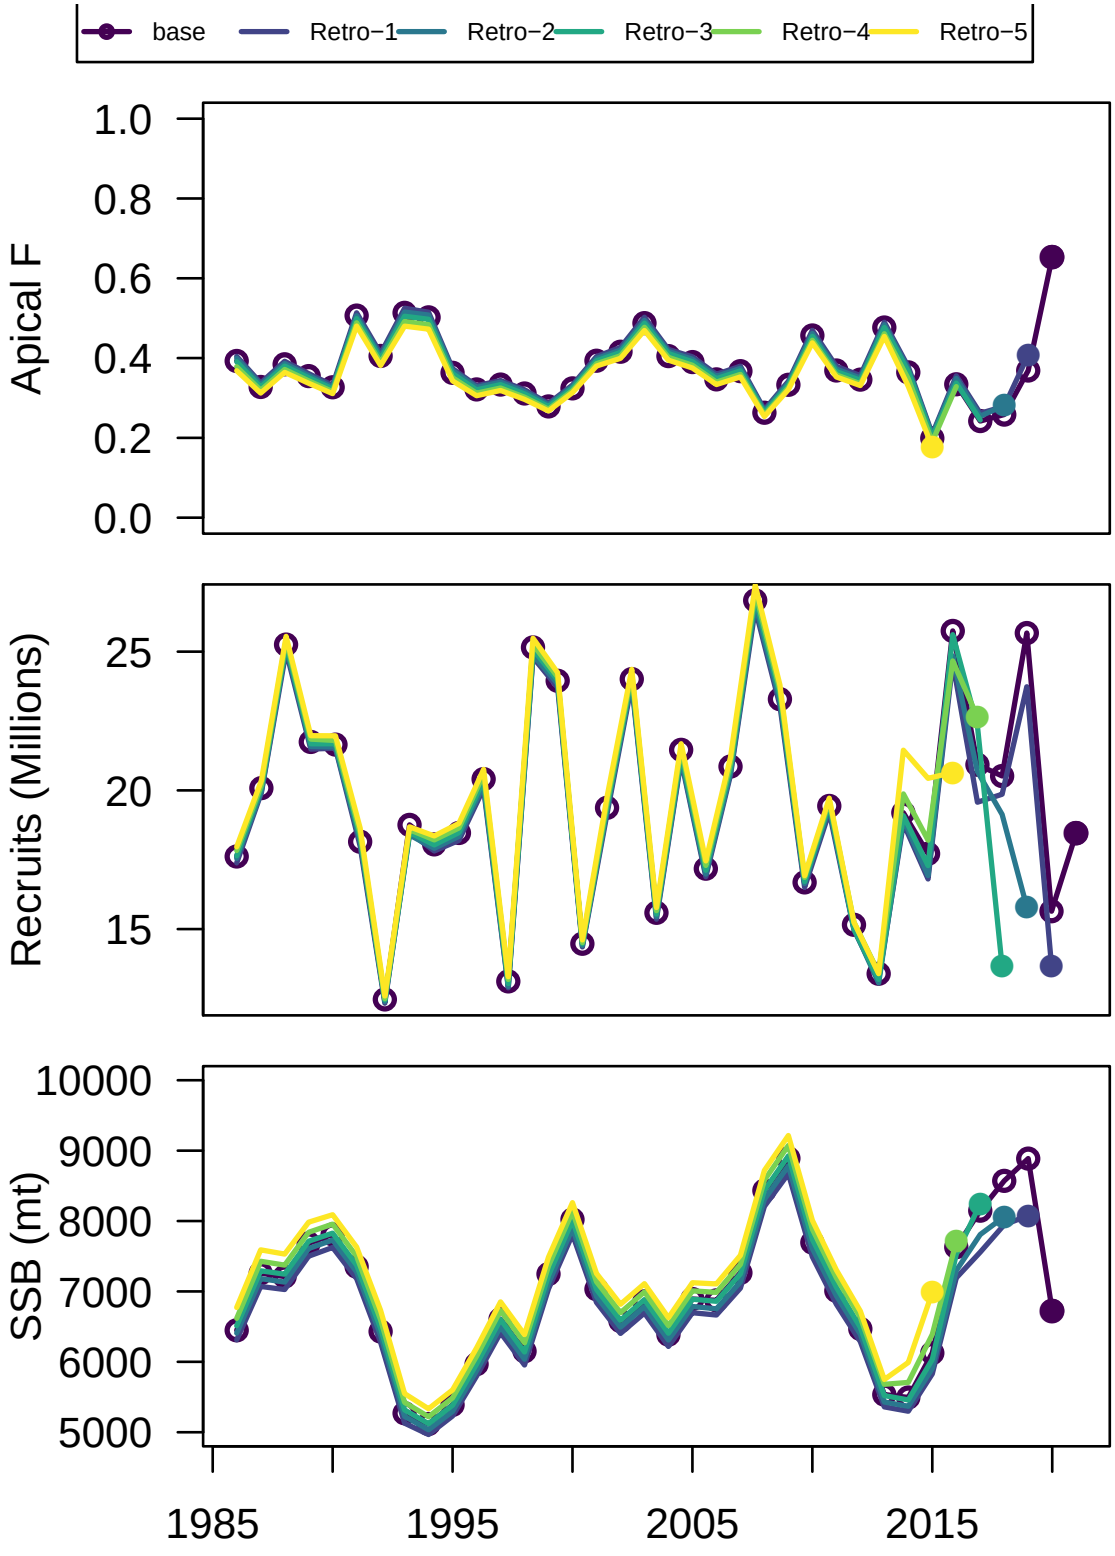

Figure 47. Retrospective analyses. Sensitivity to terminal year of data (sensitivity runs Retro 1–5). Top panel:Relative fishing mortality rate time series. Bottom panel: Relative spawning stock biomass time series.

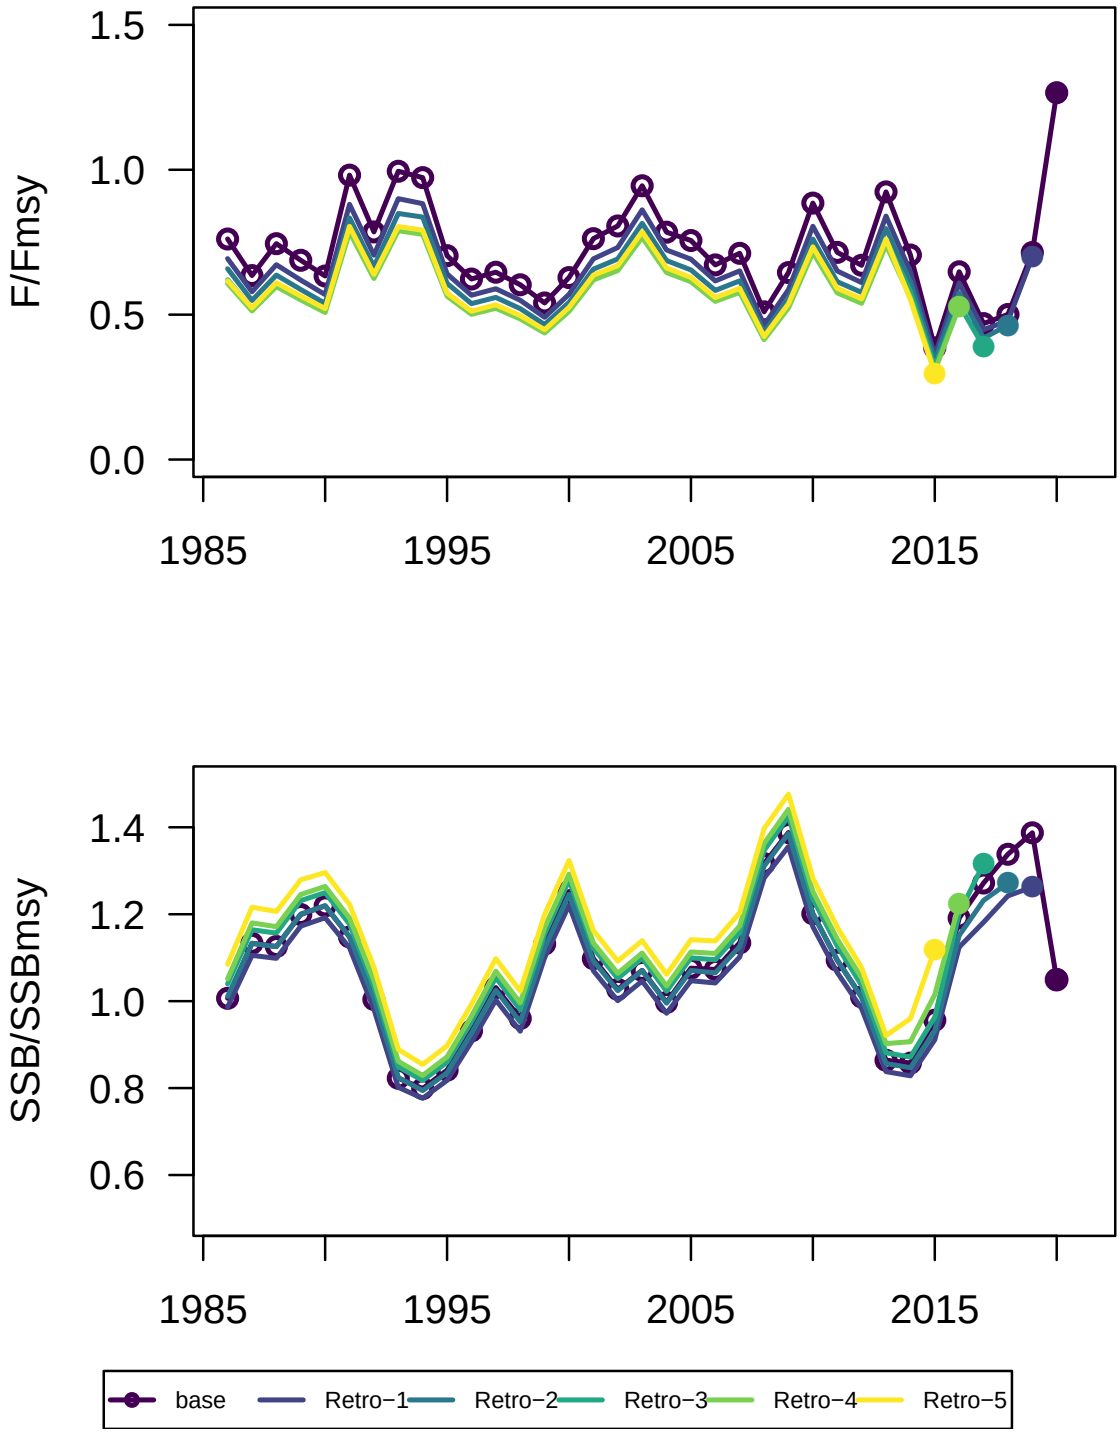

Figure 48. Projection results under scenario 1— $F = F_{\text{current}}$. Interim years (2021-2022) assume current landings based on average of the last 3 years of the assessment. Expected values (base run) represented by solid lines with solid circles, medians represented dashed lines with open circles, and uncertainty represented by thin lines corresponding to 5^{th} and 95^{th} percentiles of replicate projections. Horizontal lines mark MSY*-related quantities. Spawning stock (SSB) is at time of peak spawning.*

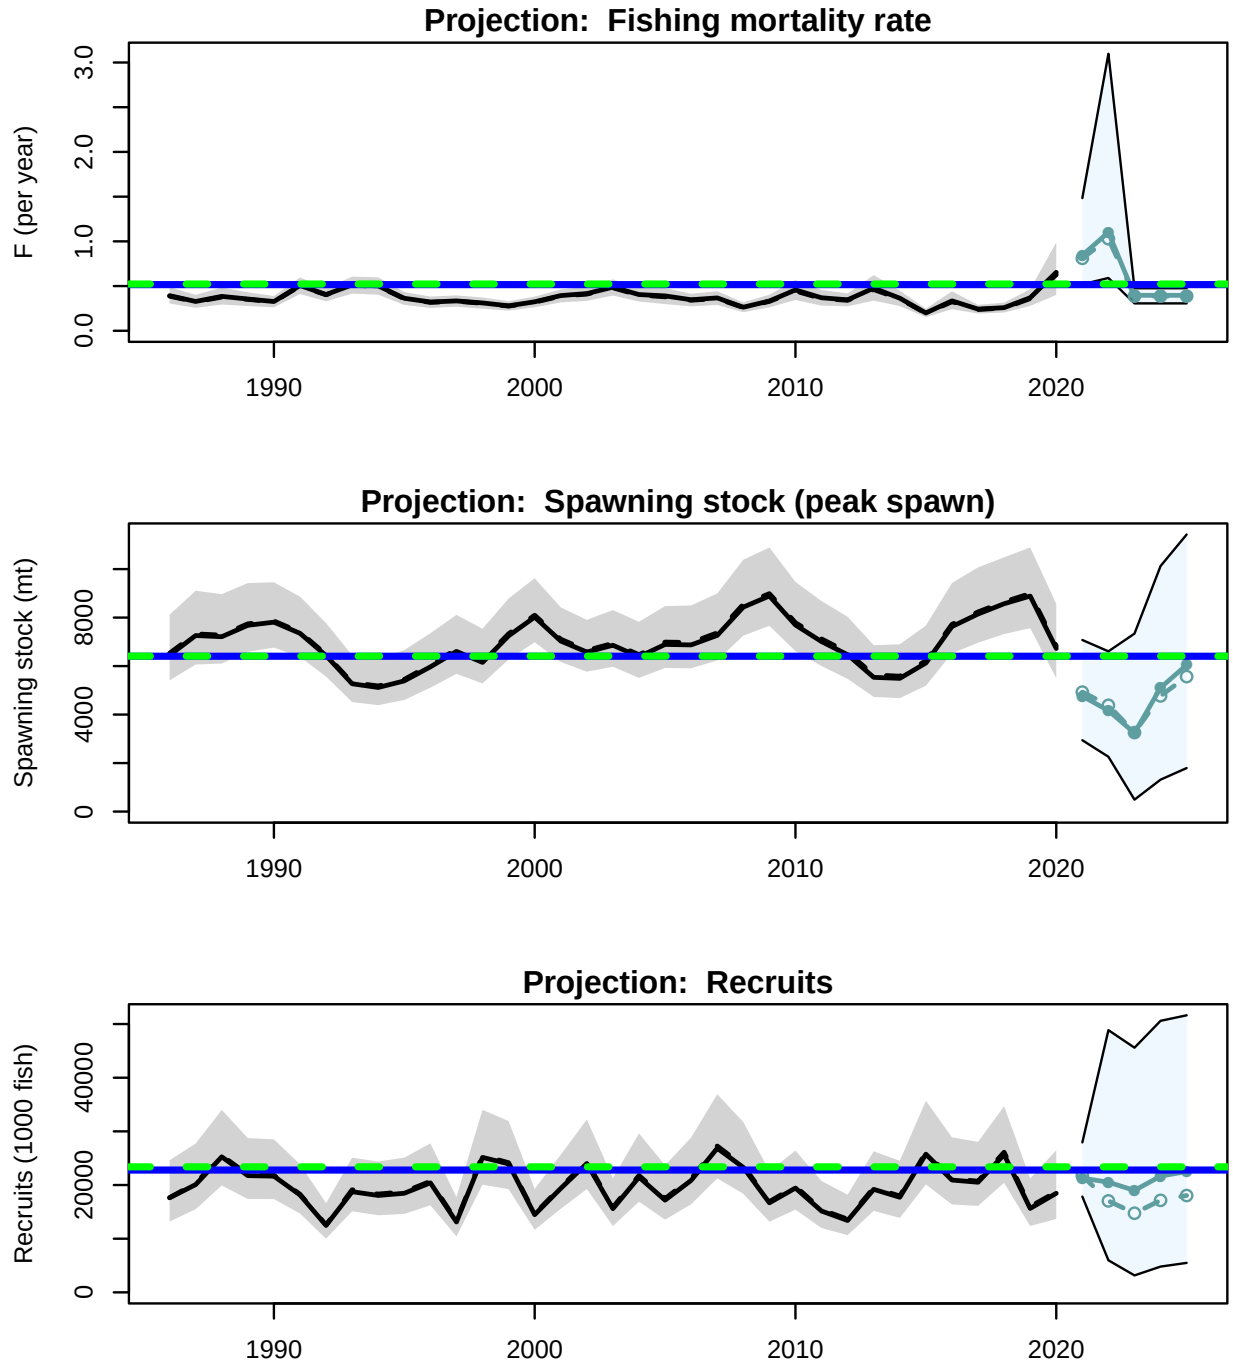

Figure 49. Projection results under scenario 2—fishing mortality rate fixed at $F = F_{\mathrm{MSY}}$. Interim years (2021-2022) assume current landings based on average of the last 3 years of the assessment. Expected values (base run) represented by solid lines with solid circles, medians represented dashed lines with open circles, and uncertainty represented by thin lines corresponding to 5^{th} and 95^{th} percentiles of replicate projections. Horizontal lines mark MSY*-related quantities. Spawning stock (SSB) is at time of peak spawning.*

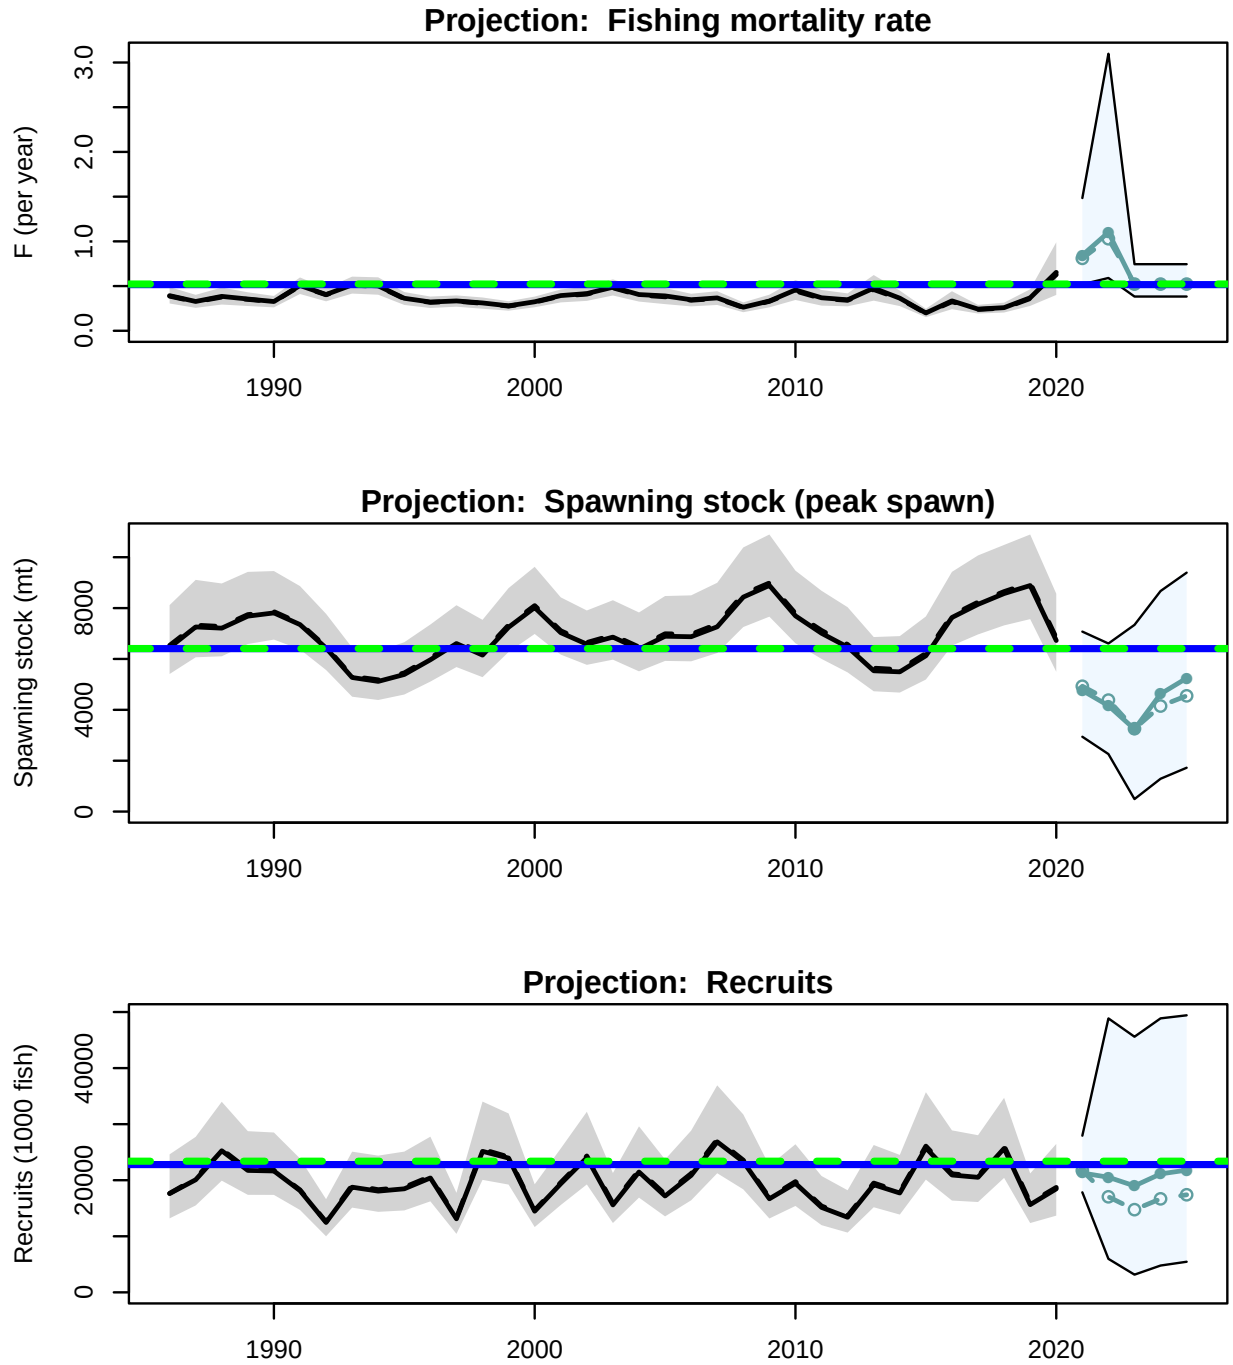

Figure 50. Projection results under scenario 3—fishing mortality rate fixed at $F = 75\%F_{\text{MSY}}$. Interim years (2021-2022) assume current landings based on average of the last 3 years of the assessment. Expected values (base run) represented by solid lines with solid circles, medians represented dashed lines with open circles, and uncertainty represented by thin lines corresponding to 5^{th} and 95^{th} percentiles of replicate projections. Horizontal lines mark MSY*-related quantities. Spawning stock (SSB) is at time of peak spawning.*

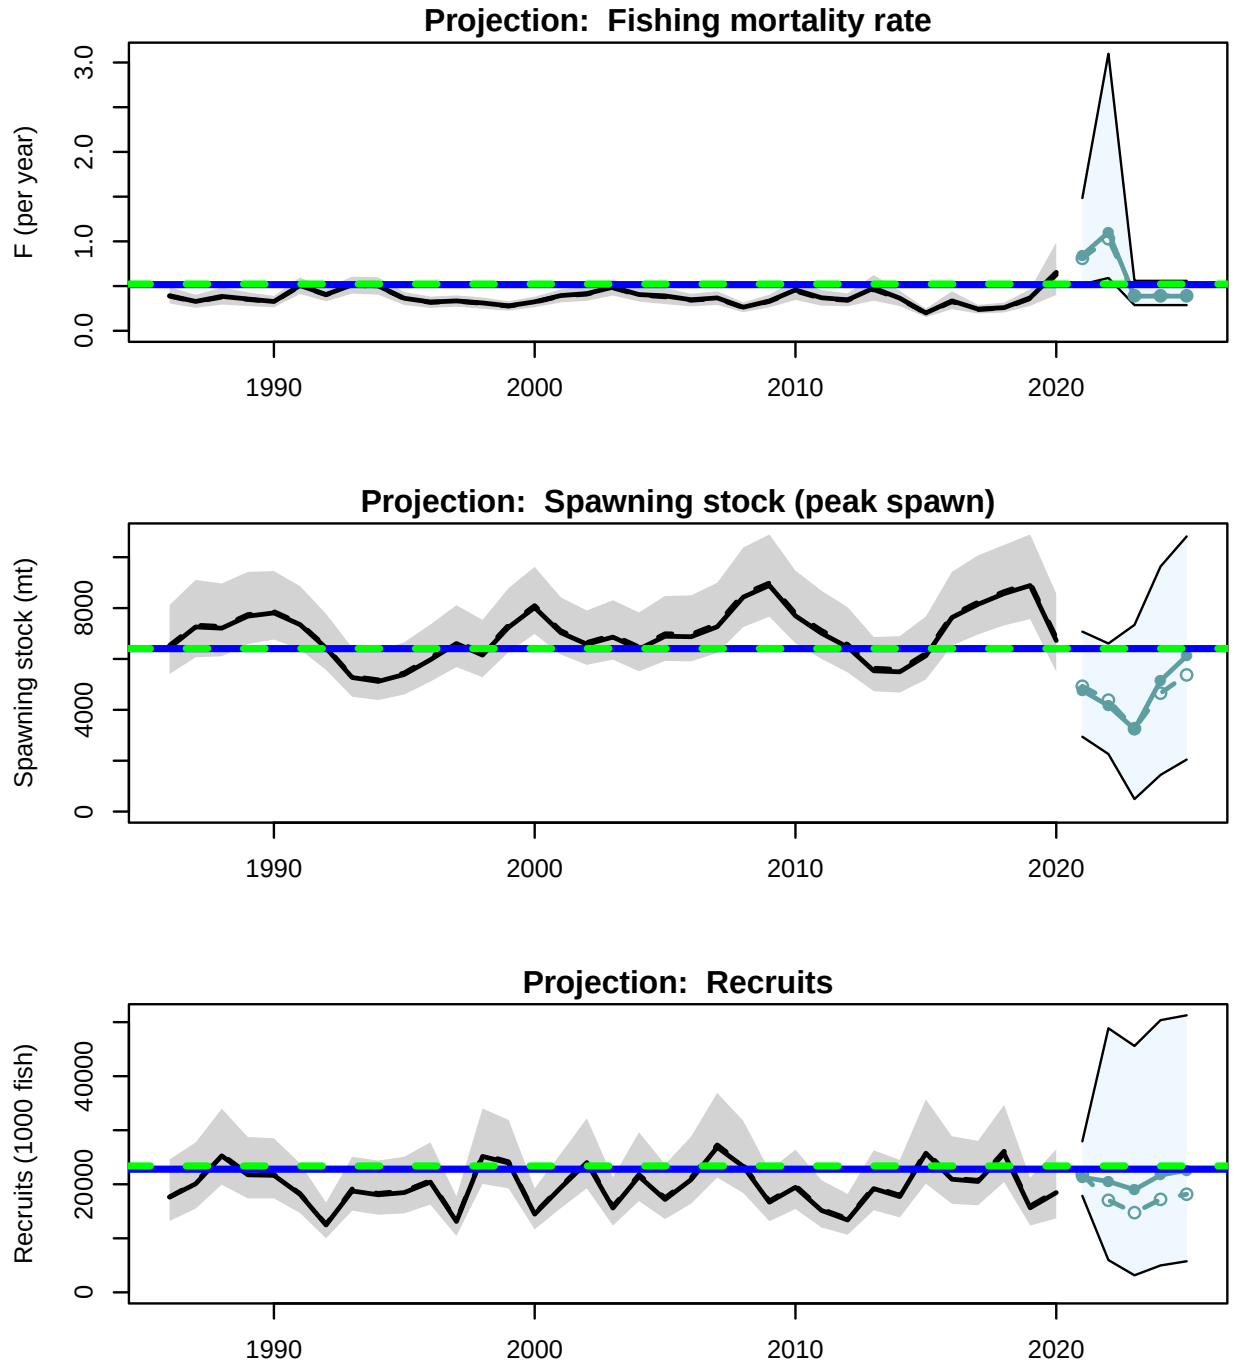

Appendix A Abbreviations and symbols

Table 27. Acronyms and abbreviations used in this report

Symbol	Meaning
ABC	Acceptable Biological Catch
AW	Assessment Workshop (here, for Spanish mackerel)
ASY	Average Sustainable Yield
B	Total biomass of stock, conventionally on January 1r
BAM	Beaufort Assessment Model (a statistical catch-age formulation)
cC	Commercial cast net fleet
cG	Commercial gillnet fleet
cH	Commercial handline fleet
cP	Commercial pound net fleet
CPUE	Catch per unit effort; used after adjustment as an index of abundance
CV	Coefficient of variation
DW	Data Workshop (here, for Spanish mackerel)
F	Instantaneous rate of fishing mortality
F_{MSY}	Fishing mortality rate at which MSY can be attained
FL	Fork length
GLM	Generalized linear model
GR	General recreational fleet (all MRIP modes and headboat)
K	Average size of stock when not exploited by man; carrying capacity
kg	Kilogram(s); 1 kg is about 2.2 lb.
klb	Thousand pounds; thousands of pounds
lb	Pound(s); 1 lb is about 0.454 kg
m	Meter(s); 1 m is about 3.28 feet.
M	Instantaneous rate of natural (non-fishing) mortality
MCBE	Monte Carlo/Boostrap Ensemble, an approach to quantifying uncertainty in model results
MFMT	Maximum fishing-mortality threshold; a limit reference point used in U.S. fishery management; often based on F_{MSY}
mm	Millimeter(s); 1 inch = 25.4 mm
MRFSS	Marine Recreational Fisheries Statistics Survey, a data-collection program of NMFS, predecessor of MRIP
MRIP	Marine Recreational Information Program, a data-collection program of NMFS, descended from MRFSS
MSST	Minimum stock-size threshold; a limit reference point used in U.S. fishery management. The SAFMC has defined MSST for Spanish mackerel as $75\%\mathrm{SSB}_{\mathrm{MSY}}$.
MSY	Maximum sustainable yield (per year)
mt	Metric ton(s). One mt is 1000 kg, or about 2205 lb.
N	Number of fish in a stock, conventionally on January 1
NC	State of North Carolina
NMFS	National Marine Fisheries Service, same as "NOAA Fisheries Service"
NOAA	National Oceanic and Atmospheric Administration; parent agency of NMFS
OY	Optimum yield; SFA specifies that OY $\leq$ MSY.
PSE	Proportional standard error
R	Recruitment
SAFMC	South Atlantic Fishery Management Council (also, Council)
SC	State of South Carolina
SCDNR	Department of Natural Resources of SC
SDNR	Standard deviation of normalized residuals
SEDAR	SouthEast Data Assessment and Review process
SFA	Sustainable Fisheries Act; the Magnuson–Stevens Act, as amended
SL	Standard length (of a fish)
SPR	Spawning potential ratio
SSB	Spawning stock biomass; mature biomass of males and females
$\mathrm{SSB}_{\mathrm{MSY}}$	Level of SSB at which MSY can be attained
TIP	Trip Interview Program, a fishery-dependent biodata collection program of NMFS
TL	Total length (of a fish), as opposed to FL (fork length) or SL (standard length)
VPA	Virtual population analysis, an age-structured assessment
WW	Whole weight, as opposed to GW (gutted weight)
YOY	Young of the year index developed from SEAMAP Coastal Trawl Survey
yr	Year(s)

6. SEDAR 78: SOUTH ATLANTIC SPANISH MACKEREL OPERATIONAL ASSESSMENT

6.1 Documents

Attachment 6a. Spanish Mackerel Summary and Background Presentation
Attachment 6b. SEDAR 78: Spanish Mackerel Revised SAR
Attachment 6c. SEFSC Spanish Mackerel Review April 2023
Attachment 6d. SSC recommended changes for assessment re-run
Attachment 6e. Setting ABCs guidance and ABC Control Rules
Attachment 6f. NOAA Fisheries Procedure 01-101-10
Attachment 6g. NOAA Fisheries Procedure 01-101-11
Attachment 5c. NOAA-NMFS 10732 SAFMC March 2023 memo

6.2 Presentation

Dr. Erik Williams, SEFSC

6.3 Overview

At the January 2023 SSC meeting, the Committee approved the scope of work for the Spanish Mackerel operational assessment re-run, which was then sent to the SEFSC. At the March Council meeting, the SEFSC determined that the SSC's recommendations regarding natural mortality, assumed recruitment and catch estimates should be considered for the next scheduled stock assessment but due to the extensive rework required would not be available for this assessment (see Attachment 5c). The Center recommended that the SSC develop ABC advice based on the current assessment and analysis completed to date. It also determined that the use of data-limited approaches such as DB-SRA or DCAC in place of the current age-structured assessment model would not be consistent with BSIA.

The SSC should determine whether the current SEDAR 78 model is sufficient for providing management advice and provide an ABC for Spanish mackerel during this meeting. Several alternate options to using the assessment projections for generating ABCs were presented in January (Equilibrium OY, yield at 75%F_{MSY}, 3rd highest landings, etc.), and the SSC should discuss the pros/cons of using these alternate methods in lieu of the assessment projections for making catch level recommendations.

6.4 Public Comment

6.5 Action

- Determine whether the current SEDAR 78 stock assessment is sufficient for providing management advice.
  - *S78 is sufficient for providing stock status (not overfished, not overfishing).*
  - *S78 is sufficient for also providing catch level recommendations using model output but not projections.*

- Provide values for OFL and ABC and make catch level recommendations for each proxy.
  - *Set ABC = Yield at 75%Fmsy from base model run (8.024 mp) (Table 22 in SAR)*
  - *Set OFL = Yield at Fmsy from base model run (8.210 mp)*

- **SSC RECOMMENDATION:**

- *In response to the SEFSC letter informing us that the Center was unable to conduct the analyses that were discussed/requested by the SSC and the Spanish Mackerel Working Group, the SSC expresses disappointment in the Center's decision. The SSC felt that the working group carefully considered workload in its discussions and the ultimate request, but appreciated Dr. Williams introduction to his presentation on the SEFSC's response. However, the SSC requests that arrangements for future assessment reviews should continue to provide the SSC the opportunity to request additional analyses or modifications to the assessment, as has been normal practice. Often, such analyses and modifications lead to improved catch advice. Equally as important, they enhance trust in the scientific advice process among Council members and stakeholders. The SSC has enjoyed a long history of working collaboratively and collegially with stock assessment scientists to provide the best possible, mutually agreed advice and hopes to continue to do so going forward.*

- *Concerns, in particular with respect to M, are still significant and were discussed extensively. The SSC discussed that the actual M may be higher than what was used in the assessment, and also refers to discussions on this topic in previous meetings and the working group report.*

- *Given this, the SSC discussed using the sensitivity run with a higher M (0.42) as the base value in the model for determining stock status and for setting ABCs. However, the SSC determined that would require reconfiguration of the model, and per Center workload would not be possible to accomplish.*

- *After considerable discussion, the SSC accepted the assessment base run as the basis for stock status determination but recommends that natural mortality (and other raised issues) should be investigated in the next assessment. The SSC concluded that the stock status determination in the Spanish Mackerel assessment base run is likely conservative because of the use of lower M, and the fact that a higher M will result in increased productivity. In addition, the biomass and harvest trends did not raise significant concerns, but the recent increase in F should be monitored.*

- *The SSC considered the above as justification to deviate from its control rule for setting ABC. The options discussed were 3rd highest (has shown poor performance in the literature), Yield at 75%Fmsy, equilibrium OY, and some others. The SSC was most comfortable with using the Yield at 75%Fmsy.*

Table 3. South Atlantic Spanish Mackerel Catch Level Recommendations

Criteria	Deterministic	Probabilistic
Overfished evaluation ($SSB_{2020}/MSST_{)}$	1.40	1.42
Overfishing evaluation ($F_{2018-2020}/F_{MSY}$)	0.77	0.74
MFMT ($F_{MSY\ proxy}$)	0.516	0.523
SSB_{MSY} (metric tons)	6406	6410
MSST (metric tons)	4804	4808
MSY (1000 lbs.)	8210	8351
Y at 75% F_{MSY} (1000 lbs.)	8024	8158
ABC Control Rule Adjustment	10%	
P-Star	40%	
M	0.35	

OFL RECOMMENDATIONS				
Year	Landed (lbs ww)	Discard (lbs ww)	Landed (number)	Discard (number)
2023	8,210,000			
2024	8,210,000			
2025	8,210,000			
2026	8,210,000			
2027	8,210,000			
ABC RECOMMENDATIONS				
Year	Landed (lbs ww)	Discard (lbs ww)	Landed (number)	Discard (number)
2023	8,024,000			
2024	8,024,000			
2025	8,024,000			
2026	8,024,000			
2027	8,024,000			

FINAL
SUMMARY REPORT
MACKEREL COBIA COMMITTEE
SOUTH ATLANTIC FISHERY MANAGEMENT COUNCIL
Saint Augustine, Florida
June 13, 2023

The Committee approved minutes from the March 2023 meeting and the agenda.

Atlantic Spanish Mackerel Stock Assessment (SEDAR 78)

At the March 2023 Council meeting, the Council discussed a letter from the Southeast Fisheries Science Center (SEFSC) stating that the revisions to SEDAR 78 requested by the SSC in January are exploratory in nature and require extensive rework. As such, they cannot be accomplished in a timely fashion. The SEFSC recommended the SSC develop ABC advice based on the current assessment. The SSC met again in April 2023 and determined that SEDAR 78 was sufficient for providing stock status and for providing catch level recommendations using model output but not projections. Dr. Jeff Buckel provided the Committee details of the SSC discussion and catch level recommendations relative to Atlantic Spanish mackerel.

The Committee discussed how to move forward with an amendment to address the new catch level recommendations and possible modifications to management measures for Atlantic Spanish mackerel. The Committee directed staff to begin work on a framework amendment to update catch levels, but to hold off on development of a full plan amendment to address management measures until after mackerel port meetings have been completed.

MOTION 1: DIRECT STAFF TO BEGIN A FRAMEWORK AMENDMENT TO UPDATE ATLANTIC SPANISH MACKEREL CATCH LEVELS BASED ON SEDAR 78 AND SSC RECOMMENDATIONS.
APPROVED BY COMMITTEE
APPROVED BY COUNCIL

Mackerel Advisory Panel Report

The Mackerel Cobia Advisory Panel met on April 21st, 2023 via webinar. The AP Chair, Ira Laks, provided a summary of Advisory Panel discussion and recommendations. The Committee noted the importance of AP member attendance given the critical topics that will be presented to the AP for discussion at upcoming meetings The importance of attendance will be noted prior to and during the fall AP meeting.

Mackerel Port Meetings

Based on recommendations from the Mackerel Cobia Advisory Panel, the Council directed staff to begin work on a plan to conduct port meetings for king and Spanish mackerel to gain a comprehensive understanding of the fisheries to improve management efforts. Staff presented a discussion document for the Council to review the current CMP FMP goals and objectives, port meeting goals and objectives, draft timeline, and proposed planning team. The Committee provided the following input:

- Gather more information on CMP FMP Objective 6 (minimize waste and bycatch in the fishery) during port meetings. Discuss why king or Spanish mackerel may be discarded by each sector and how stakeholders would like discards to be considered in management.

- Do not present Objective 5 (Atlantic Spanish mackerel allocations) during port meetings because it requests the use of data that is no longer supported, and it is the Council's intent to remove the objective during the next update.
- Add the following to the goals and objectives for port meetings:
    - Identification of underserved communities and equity and environmental justice concerns.
    - Consideration of interjurisdictional management and cooperation with other councils and the Atlantic States Marine Fisheries Commission (ASMFC).
- Consider whether the Gulf States Marine Fisheries Commission (GSMFC) may be beneficial partners if port meetings are conducted throughout the Gulf of Mexico.

DIRECTION TO STAFF: DO NOT BRING OBJECTIVE 5 OUT FOR DISCUSSION DURING PORT MEETINGS AS IT IS NO LONGER A VIABLE OBJECTIVE.

DIRECTION TO STAFF: ESTABLISH A PORT MEETING PLANNING TEAM AS DESCRIBED IN THE DISCUSSION DOCUMENT.

King Mackerel Tournament Landings

At their December 2022 meeting the Council requested NMFS provide information on king and Spanish mackerel tournament landings over the last ten years and how those landings were accounted for against the annual catch limit. The SEFSC worked with the state agencies to provide these landings and present them to the Council. The Committee provided the following input:

- The Committee would like more information on what charities are receiving money through the sale of donated tournament fish.
- Stakeholders have expressed concerns to the Committee about the king mackerel stock and the role tournaments may be playing in fishery. The Committee requested that the Mackerel Cobia AP discuss these tournaments, their importance to communities and how the sale of fish from these tournaments affects their fishing activities.

Topics for the Fall Mackerel Cobia Advisory Panel Meeting

The Mackerel Cobia Advisory Panel (AP) is scheduled to meet in Charleston, SC this fall. The Committee approved the following topics for discussion:

- Atlantic Spanish mackerel catch level recommendations,
- Mackerel Port Meetings,
- King mackerel tournament landings,
- Citizen Science update,
- Atlantic king mackerel fishery performance report update.

The Committee also noted that the fall meeting may be an appropriate time for the ASMFC's Spanish mackerel AP to meet jointly with the Council's Mackerel Cobia AP.

Other Business

Note: Council staff drafts the timing and task motion based on Committee action. If points require clarification, they will be added to the draft motion. The Committee should review this wording carefully to be sure it accurately reflects their intent prior to making the motion.

Timing and Task(s)

MOTION 2: ADOPT THE FOLLOWING TIMING AND TASKS:

1. Begin work on a framework amendment to update Atlantic Spanish mackerel catch levels based on SEDAR 78 and SSC recommendations.
2. Continue development of port meetings including organizing a planning team to facilitate collaboration with other councils and commissions.
3. Convene an in-person meeting of the Mackerel Cobia AP this fall to discuss the topics listed above and note the importance of attendance.

APPROVED BY COUNCIL
