Comment

Atlantic Menhaden Board:

Recently, Ault and Luo (2026) published a paper that purported to provide a new estimate of natural mortality that, if used, would substantially change the estimated biomass of menhaden in the stock assessment. They further claimed that their study was an improvement over the estimates in Liljestrand et al. (2025). Taken at face value, the Ault and Luo (2026) study casts doubt on the accuracy of the 2025 stock assessment.

As a co-author of Liljestrand et al. (2025), I have reviewed the work in Ault and Luo (2026) and found several fatal flaws such that the information in that paper should not be considered best available science. The main flaws are:

1) The models used by Ault and Luo (2026) do not produce statistically valid estimates. I have rerun their models that are publicly posted on GitHub (https://github.com/bigjawfish/Menhaden_MMR_Model) and found that they do not meet standard diagnostics for determining whether results from a Bayesian model are valid. This is not surprising because previous research on this type of model indicates that the Ault and Luo (2026) model should have problems with parameter estimation.

2) Ault and Luo (2026) ignore the empirical data on magnet efficiency from experiments that were done by putting tagged menhaden directly into the reduction plants to determine the fraction of tags that were recovered (nearly 100,000 fish in nearly

1,000 separate experiments). Liljestrand et al. (2025) used these data to inform their model, which is a better approach.

3) Ault and Luo (2026) distort the literature on the maximum age of Atlantic menhaden. Ault and Luo (2026) state, “More than five decades of ageing data encompassing over half a million Atlantic menhaden indicate that the species regularly attains ages of at least 10–11 years (Schueller et al., 2014, 2021; SEDAR 69, 2019).” That statement is misleading and incorrect. No Atlantic menhaden have been aged to age-9 or older since 1964, despite >500,000 menhaden being aged during 1955-2023. These early high ages are only present in the first ten years of the ageing program when ageing methods were still being developed, and they had a different set of agers than after 1968. A more realistic estimate of the maximum age is likely 6-8. Age 8 is the oldest observed age since 1968 with only two observations. Only twelve fish have been age-7 since 1968, and 155 fish have been aged to 6 (out of more than 300,000).

These flaws are similar to those identified by the ASMFC Atlantic Menhaden Technical Committee when they reviewed Ault and Luo’s work previously and comments (March 4, 2025) that I also made to Ault and Luo over the past several years. However, Ault and Luo chose not to address them. The stock assessment should continue to be used as the best science to manage this stock. My co-authors and I plan on submitting a rebuttal to the Ault and Luo (2026) article soon.

Sincerely,
Mike Wilberg
Professor
University of Maryland Center for Environmental Science

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I strongly support reducing the Chesapeake Bay reduction-fishery cap by **50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

I have lived in St. Mary's County since 2008 and am lucky enough to have an osprey nest just off my pier. We used to have two to three chicks annually fledge and migrate at the end of the season. Now, we are lucky to have one chick and the last three years they have all starved before fledging.

The evidence points to a decline in the number of menhaden that the ospreys, striped bass and other marine life in the Chesapeake watershed depend upon for their survival.

It is both when and where those fish are removed that matter. A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource.

The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. **One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users.**

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just one Virginia based fishing company.

The Chesapeake Bay is not simply a location on a fisheries management map. It is a complex and interconnected ecosystem, and menhaden are one of its essential links.

We should not wait for further deterioration before taking action. There is no time for additional five-year studies to delay the decision. The severe drop in nesting pairs and the lack of surviving chicks will not replenish the specicies enough to survive that long.

As someone who lives here, fishes and sails these waters, swims in them, and cares deeply about the wildlife that depends upon them, I believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.

Thank you for your consideration.

Sincerely,

Chris Allen

Subject: [External] menhaden

Hi. I am very concerned about the loss of the osprey population due to the depletion of menhaden. We need stricter limits on how many menhaden can be caught so we can protect the osprey and the ecosystem at large. I hope you will support limits and prevent Cooke Inc. from further decimating the osprey population. Thank you

Amy Allen-Chabot

Subject: Re: [External] Re: Public comment document / portal / submission

Mr. Boyle,

Thank you. Here is my comment as a Maryland resident.

Troy Anderson
Timonium, MD

I am writing in strong support of Option B4, the full 50% reduction of the Chesapeake Bay Cap to 25,500 mt, along with measures that shift harvest later in the season. This is the most effective and least ambiguous approach to protecting the Chesapeake Bay ecosystem and ensuring equitable access to menhaden for Maryland's fisheries.

I am very concerned about this issue in the Bay. I fish and have taught my daughters (and later, their boyfriends) how to fish the Bay. In recent years, it is clear that Stripers are getting skinnier, and other anglers are telling me the same story. There are published papers on how predators are being negatively impacted (From Osprey to native fish in the Bay). I thank you for considering my comment. I tried to organize it based on the information provided.

My comments / recommendations is as follows:

1. Option B4 is the strongest and clearest ecological choice

The Draft Addendum states:

"Sub Option B4: Reduce by 50% to 25,500 mt."

This reduction is necessary because the Chesapeake Bay's forage base is under sustained ecological stress. The Ecological Reference Points (ERP) framework—ASMFC's ecosystem-based management system for Atlantic menhaden—shows that predator species such as striped bass, bluefish, and weakfish are below target biomass and experiencing poor body condition due to forage limitations. Under the ERP framework, higher harvest levels increase the probability of exceeding both the ERP fishing mortality target and the ERP threshold, as shown in the Draft Addendum's risk tables.

Maryland's striped bass juvenile index has produced seven consecutive below-average year classes, a

clear indicator of ecosystem instability. Peer-reviewed research from the University of Maryland Center for Environmental Science has documented osprey reproductive failure in the lower Bay driven by menhaden scarcity. These findings demonstrate that current harvest levels are not sustainable for the broader food web.

2. Seasonal quota periods must shift harvest later (Options B2 or B3)

The Draft Addendum explains the purpose of quota periods:

"Alleviate a concentration of reduction harvest that may prevent menhaden from distributing throughout the Bay."

Options B2 and B3 best accomplish this by reducing early-season industrial harvest and allowing menhaden to move into Maryland waters, supporting predators, recreational anglers, and small-scale commercial fisheries.

3. Support for overage paybacks and late-season rollovers (Option B)

The Addendum's example shows how overages can be corrected:

"Period 1 would be reduced by 2,000 pounds and Period 3 would be increased by 2,000 pounds."

Mandatory paybacks and rollover only into later periods reinforce the ecological goal of protecting early-season distribution.

4. Regular Bay Cap review is essential (Section 3.3, Option B)

The ERP framework demonstrates that ecosystem conditions can shift rapidly. A three-year review cycle ensures the Bay Cap remains aligned with predator needs and updated ERP risk analyses.

5. Maryland's recreational and charter economy depends on menhaden

NOAA Fisheries reports that recreational fishing in Maryland generates over $1.4 billion annually and supports more than 12,000 jobs. Maryland's charter fleet alone contributes over $100 million in annual economic activity.

By contrast, the reduction sector is geographically concentrated in a single Virginia county and represents a small fraction of the Bay's total fisheries economy. Protecting forage availability is far more economically consequential for Maryland and the broader Chesapeake region.

I urge the Board to adopt Option B4 and the strongest possible combination of seasonal distribution, overage controls, and regular review. These measures are necessary to protect the Chesapeake Bay ecosystem and ensure sustainable, equitable use of this shared resource.

Best regards,
Troy Anderson

Subject: [External] ASMFC menhaden public hearing

I recently received a thank you from your organization thanking me for attending your Menhaden public hearing. THANK YOU FOR ALLOWING THE PUBLIC TO LISTEN AND COMMENT!

I have fished the middle western portions of the Chesapeake Bay, mostly around Gwynns Island and the Piankatsnk River, for the past 50 years. I have personally observed the significant decline in fish during that time period. Everything from trout, redfish, spot, and croakers. I used to kayak fish along the shoals at the Hole in the Wall. It was so enjoyable to see 5 or 6 ospreys diving for fish in that area and I had pretty good luck catching both reds and trout. Not any more as there are no more fish. Haven't caught a "red" or legal trout in over 2 years. My neighbor who line fishes almost every day has also see a similar decline in fish. Now I see only one or two ospreys desperately searching for food along our shoreline.

In my opinion the problem is much larger than just Menhaden. It's commercial overfishing. We used to have good fishing, but for the past 7 or 8 years big commercial netter boats have been operating out of Milford Haven almost every day in good and bad weather. No controls, and if there are, no enforcement. This past September they were not sending all their boats out-not sure why-could be the price of diesel? Obviously it wasn't economically feasible. But as I stated above there are very few fish.

In summary the "canary in the coal mine" is not just the significant decline in Menhaden, or the starving ospreys, but the overall decline in fish caused by a combination of factors, environmental, overfishing, and unwillingness of some state fishing commissions to take effective actions. Please, take appropriate actions to restore our fisheries.

Respectfully,
Roger Anderson

Public Testimony - Atlantic Menhaden Draft Addendum II

Atlantic States Marine Fisheries Commission
Atlantic Menhaden Management Board

Annie Sokoloski
Voices of the Fleet
Lubec, Maine

I have spent decades working in commercial seafood operations and along Maine's working waterfront. I understand that responsible fisheries management has to account for the resource itself, but I also understand the realities behind the numbers: fishermen, vessels, processing capacity, weather, markets, migration, bait supply, and communities whose livelihoods depend upon decisions made by fisheries managers.

Although Draft Addendum II focuses specifically on the Chesapeake Bay reduction fishery, Atlantic menhaden are a coastwide resource. What happens in Chesapeake Bay deserves the attention of fishing communities throughout the Atlantic states.

And I believe there is one distinction that should remain at the center of this discussion:

There is evidence of concern in Chesapeake Bay. There is not yet evidence establishing a single cause.

The Draft Addendum documents legitimate warning signs. Maryland's Chesapeake Bay pound-net menhaden harvest declined by 60% in 2024 compared with the 2018-2022 average. Notable declines in pound-net catch per unit effort were also observed in Maryland, Virginia, and the Potomac River fisheries. A fishery-independent survey in the Choptank River showed a substantial decline in adult menhaden abundance in 2024 that remained low in 2025. Those observations deserve serious attention.

But the Draft Addendum is equally important for what it says we do not yet know.

ASMFC acknowledges that sufficient scientific information is not currently available to comprehensively characterize menhaden abundance and distribution throughout Chesapeake Bay or determine the influence of fishing pressure on menhaden within the Bay.

Menhaden availability can be affected by fishing pressure. It can also be influenced by overall abundance, population structure, spatial and temporal distribution, environmental conditions, habitat suitability, and predation pressure. The Draft recognizes those possibilities.

That brings me to the principle that guides my comments:

> **I am not opposed to precaution. I am opposed to presenting precaution as certainty.**

If the Board determines that precautionary action is warranted, then take precautionary action - but call it what it is.

Explain why that particular level of precaution was selected. Be equally clear about what the science tells us and what it cannot currently establish. And commit to revisiting the decision as better Chesapeake-specific information becomes available.

Precaution should protect the resource while the science catches up. It should not become a substitute for the science.

The Chesapeake Bay Cap

The existing Chesapeake Bay reduction-fishery cap of 51,000 metric tons was not established as a scientifically determined biological threshold for Chesapeake Bay. It approximated average Bay reduction harvest during 2012-2016. The Draft also acknowledges that there is no scientifically determined Chesapeake-specific forage threshold upon which the current Bay Cap is based.

The Board is now considering maintaining the existing cap or reducing it by 10%, 20%, 30%, or 50%, potentially reducing the cap to 25,500 metric tons.

Those are materially different management decisions.

If the Board chooses one of those reductions, fishermen and the public deserve to understand why that particular percentage was selected.

A 10% reduction, a 20% reduction, and a 50% reduction cannot all represent the same biological determination.

If the science cannot presently identify a precise Chesapeake-specific threshold, then the selected percentage should be described accurately as a management judgment about the appropriate level of precaution under uncertainty.

There is nothing inherently wrong with making such a judgment. Fisheries managers are sometimes required to act before every scientific question has been answered. But transparency about the basis for that decision matters.

Linking the Bay Cap to the Coastwide TAC

I am particularly cautious about permanently linking the Chesapeake Bay Cap to the coastwide Total Allowable Catch.

A one-time precautionary reduction can be evaluated and revisited as additional Chesapeake-specific science becomes available. An automatic formula is different.

It establishes an ongoing management relationship between two measures that were created for different purposes.

The coastwide TAC limits total removals across the fishery and is informed by coastwide stock assessments and ecosystem reference points. The Chesapeake Bay Cap limits reduction harvest within a specific geographic area and historically has been based largely upon recent landings rather than a scientifically determined Chesapeake-specific forage threshold.

Under the options contained in this Addendum, future changes in the coastwide TAC could automatically produce corresponding percentage changes in the Chesapeake Bay Cap, subject to whatever upper and lower limits the Board selects.

Before establishing that automatic relationship, I believe the Board should demonstrate the scientific basis for assuming that a percentage change in coastwide TAC should produce a corresponding percentage change in the amount of reduction harvest appropriate within Chesapeake Bay.

Changing today's number and changing the formula that determines tomorrow's number are not the same decision.

They should not be treated as though they are.

Timing Matters Too

I also believe the Board is right to examine the timing and concentration of harvest separately from total harvest.

In 2023 and 2024, more than half of Chesapeake Bay reduction landings occurred during approximately a six-week period in midsummer. The Draft raises the legitimate question of whether concentrating that much harvest into a relatively short period could affect availability to other fisheries and predators.

But this is where management must also recognize how fisheries actually operate.

Fish do not follow a management calendar.

Having worked for decades in commercial seafood operations, I understand that biological availability, migration, weather, vessel operations, processing capacity, markets, and regulatory calendars do not always align neatly.

The historical information presented in this Addendum shows significant differences between when the fishery has actually operated and some of the seasonal allocations now being considered.

If seasonal quota periods are adopted, they should contain enough flexibility to respond to actual conditions. A fisherman should not be penalized simply because fish were available during a different part of the season than a management calendar anticipated.

Require the Three-Year Review

On this issue, I do have a clear preference.

I support the option requiring the Board to revisit these measures every three years.

The Draft Addendum specifically provides the Board with the option of establishing a three-year review schedule.

If these measures are adopted because uncertainty warrants precaution today, then the Board has an equal responsibility to examine them again as additional information becomes available.

That review should consider new Chesapeake-specific research, fishery-independent information, fishery performance, changes in distribution and availability, and what managers have learned since implementation.

Precautionary measures adopted while the science is developing should not become permanent simply through inertia.

If the evidence later supports stronger measures, the Board should have the willingness to strengthen them. If the evidence supports relaxing them, the Board should have the willingness to do that as well.

That is what adaptive fisheries management should look like.

> **Protect the resource. Protect the integrity of the science. And recognize the people whose livelihoods depend upon the decisions made in this room.**
>
> **Those responsibilities are not mutually exclusive. Good fisheries management requires all three.**

Thank you for the opportunity to comment.

James Boyle

From: Chris Arias <chris@oceanresearchproject.org>

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear James Boyle and The Atlantic Menhaden Management Board

I'm a member of the Board of Directors of Ocean Research Project (ORP), although I speak for myself and not on the behalf of ORP, an organization dedicated to studying the impacts of human-induced stress on the world's oceans.

In 2024, ORP conducted a Chesapeake Bay-wide survey of plastic pollution, the findings of which were subsequently included in the Chesapeake Bay's annual report card. Our research found that microplastics and microfibers are pervasive throughout the Bay, highlighting just one of the many pressures affecting this vital ecosystem.

The Chesapeake Bay faces multiple, interconnected stressors, including plastic pollution, habitat degradation, and fishing pressure. While no single regulatory action can solve all of these problems, I believe that taking meaningful steps to address individual stressors—particularly the management of Atlantic menhaden, a critical forage fish—can help improve the Bay's overall health and resilience.

The proposed menhaden management measures offer an opportunity to take a precautionary approach, ensuring that sufficient menhaden remain available to support the Bay's food web, other fisheries, and the wildlife and communities that depend on them. By better managing this resource, we can help preserve the Chesapeake Bay's ability to sustain commercial and recreational fishing, provide jobs, and remain a source of enjoyment for generations to come.

I urge the Commission to adopt the **50% reduction option for the Chesapeake Bay menhaden harvest cap**, along with effective seasonal harvest limits, as a meaningful step toward protecting this essential forage fish and the broader ecosystem that depends on it. Given the multiple, interconnected stressors facing the Chesapeake Bay, a precautionary approach to menhaden management is both reasonable and necessary. Reducing harvest pressure would help safeguard the availability of menhaden for the Bay's predators, support the health of the food web, and contribute to the long-term sustainability of the Bay's fisheries and wildlife. While no single action can reverse the Bay's decline, stronger science-based management can make a real difference. We owe it to future generations to take meaningful steps now to ensure the Chesapeake Bay remains a healthy, productive resource for wildlife, fishing communities, local economies, and everyone who depends on and enjoys its waters.

September 27, 2026

To the Atlantic States Marine Fisheries Commission,

I am a committed conservationist and I have a particular focus on ospreys and other bird species. As a member of the Connecticut Audubon Society, I have been an osprey nest monitor for a number of years. Since 2014, the CAS has run the Osprey Nation Program in partnership with CTDEEP. It monitors the size, productivity and health of Connecticut's osprey population. Approximately 450 volunteer stewards monitor nearly 1,000 nests each season. In 2025, the program recorded its lowest breeding success ever. While we are waiting for the final report, it is already evident that this year is even more devastating. (Reports available online and upon request).

Menhaden play a key role in supporting Connecticut's osprey populations and it is becoming apparent that the decline in migrating menhaden populations from the Chesapeake Bay are having an effect on our waters in the Long Island Sound. This year, Connecticut's osprey monitors witnessed first-hand, too many young osprey starving to death because of inadequate supplies of menhaden.

I urge you to take the following decisive action:

Adopt Sub Option B4: a one-time 50% reduction in the bay cap

Adopt Quota Period B2: 25-25-50% allocations to delay seasonal harvests

Thank you for your serious consideration of adjusting the harvest quotas and timing to ensure the sustainability of osprey and other species within the menhaden food chain.

Amanda Baker

Public Comment on Draft Addendum II to Amendment 3 of the Atlantic Menhaden Interstate FMP

Chair and Members of the Atlantic Menhaden Management Board:

Thank you for the opportunity to provide public comment on Draft Addendum II to Amendment 3 of the Atlantic Menhaden Interstate FMP. After reviewing the alternatives presented in the Addendum, I support the following combination of options:

Section 3.1 – Chesapeake Bay Reduction Fishery Cap Amount Option C-Link Chesapeake Bay Cap to the coastwide TAC
Sub-option C1c – 21.8% of the coastwide TAC
Sub-option C2a – Maximum Bay Cap of 51,000 mt with no lower limit

This approach links the Chesapeake Bay Cap to the coastwide TAC while establishing a meaningful reduction from the current Bay Cap. A maximum of 51,000 mt prevents the Bay Cap from increasing above its current level while allowing it to decline proportionally if the coastwide TAC is reduced. C1c provides a 20% reduction from the current Bay Cap while maintaining a direct relationship between the Bay Cap and changes in the coastwide TAC.

Section 3.2.1-Quota Periods-Option B2-Three approximately equal-length quota periods with a 25% / 25% / 50% distribution

This option places greater emphasis on delaying harvest until later in the season by limiting the first two quota periods to 25% of the annual Bay Cap each and reserving 50% for the final period. Historical landings have been concentrated disproportionately in the middle portion of the season, while substantially less harvest has historically occurred during the final period. In my view, B2 is therefore the option most consistent with the stated objective of moderating reduction-fishery landings during the beginning and middle of the season as a precautionary measure supporting the availability of menhaden to other fisheries and predators.

Section 3.2.2 – Quota Period Accountability – Option B – Quota-period overage accountability

Among the alternatives presented, I support Option B because it provides accountability for quota-period overages rather than treating the separate quota periods as having no consequence unless the overall annual Chesapeake Bay Cap is exceeded. I do not support the underage sub-option that would redistribute unused quota from the first period into the middle period. Given the objective of moderating harvest during the beginning and middle portions of the season, shifting unused early-season quota into the middle period would work against that objective.

Section 3.3 – Bay Cap Revisit Provision – Option B – Revisit the Chesapeake Bay Cap every three years

I support periodic review of the Bay Cap and believe a three-year revisit provision is appropriate. The Chesapeake Bay reduction fishery and the operation of the new quota-period structure should be evaluated over time to determine whether these measures are achieving their intended management objectives and whether further adjustment is warranted.

Taken together, Option C, C1c, C2a, Option B2, the Section 3.2.2 Option B accountability approach, and the three-year revisit provision provide the most balanced approach among the alternatives presented in Draft Addendum II. This combination links the Chesapeake Bay Cap to the coastwide TAC, prevents the Bay Cap from increasing above its current level, provides for accountability within the quota-period structure, and places greater emphasis on moderating harvest earlier and in the middle of the season.

I have also attached a separate memorandum addressing the Board's earlier consideration of a no-rollover provision. That memorandum does not request that Draft Addendum II be reopened or delayed. Rather, it explains why I believe the decision not to retain that provision was a missed opportunity and why the issue should remain relevant to future evaluation of the quota-period structure.

Attachment: Comment on the Approved and Subsequently Rescinded No-Rollover Provision

The Board previously considered and approved a motion to add an option for a no-rollover provision to the quota-period structure. That motion was subsequently reconsidered and failed. In my view, walking back the inclusion of an option for a no-rollover provision was a missed opportunity.

It is important to note that the Board initially voted to include a no-rollover option in the draft specifically to provide the public and the Board with a more complete range of management alternatives for consideration. I believe the decision not to include a no-rollover option in the draft Addendum was ill-advised and warrants comment because it directly affects how the staged quota-period structure included in the Addendum might operate.

Separate quota periods should not simply divide the annual Chesapeake Bay Cap into administrative segments. The timing and distribution of harvest have management and biological significance, including the potential benefit of moderating harvest pressure earlier in the season and allowing menhaden greater opportunity to move out of Chesapeake Bay. Allowing unused quota from an earlier period to automatically become additional harvest opportunity later in the season can undermine the purpose of establishing separate quota periods by shifting harvest opportunity away from the period in which it was originally allocated.

An underage during a quota period should not necessarily be viewed simply as lost harvest opportunity or as a punitive consequence for the fishery. If menhaden are not available in sufficient quantity to support harvest during a particular period, that underage may itself provide useful information concerning changes in their availability and distribution within Chesapeake Bay. As was noted during the Board's proceedings, it may serve as a "canary in a coal mine." Automatically converting unused quota into additional harvest opportunity later in the season risks disregarding that signal. The fact that an unused allocation may not remain available later in the season should not, by itself, be characterized as punitive. A no-rollover approach would not impose an additional penalty beyond the annual Chesapeake Bay Cap. Rather, it would give practical meaning to the decision to establish separate quota periods by recognizing that the timing and distribution of harvest can themselves have management and biological significance.

For these reasons, I believe abandoning the no-rollover provision was a missed opportunity. I am not suggesting that Draft Addendum II should now be delayed or reopened. Rather, the operation of the staged quota-period structure should be evaluated with this issue in mind. If experience demonstrates that rollover alters the intended distribution of harvest or undermines the management benefits of establishing separate quota periods, the Board should be prepared to revisit the issue.

Respectfully submitted,

Joseph Beneventine
Recreational Angler NY

Subject: [External] DRAFT ADDENDUM II TO AMENDMENT 3 OF THE ATLANTIC MENHADEN INTERSTATE FISHERY MANAGEMENT PLAN

Hi. Although I am based in England, I have been conscientiously observing live cams on osprey (Pandion Haliaetus) specifically in the New Jersey area since 2019.
On a particular nest at Barnegat Light, the menhaden catch by ospreys over the last two years, the usual prey, has reduced by more than 80%.

In many nests, this has led to:
1. Failure in re-bonding due to the males being unable to provide for the females, leading to no or fewer eggs, and non-viable eggs.
2. Adults abandoning nests due to menhaden shortage.
3. Hatched chicks - significantly decreased in number anyway - dying of starvation.
4. Mature birds having to subsist on lesser-quality fish, e.g. flounder, thus not giving them the sufficient nutrition required for migration. (Several known adults have already failed to return.)

This food stress amongst ospreys is already extreme in its consequences and it can only be compared to the dire situation in the 1970s when DDT was prevalent, leading to the near-extinction of this species on the eastern seaboard of the USA.

Please consider a total moratorium on the harvesting of this vital fish species to allow for regeneration.

Yours sincerely,
Roo Bentley.

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I strongly support reducing the Chesapeake Bay reduction-fishery cap by **50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

I have lived in St. Mary's County since 1996 and have developed a deep personal connection to the Chesapeake Bay. I am an avid boater and I spend considerable time on and around the Bay. I care deeply about the wildlife that depends upon it, particularly osprey, striped bass, and other species whose survival is tied to a healthy and abundant forage base.

We are seeing warning signs that should demand a precautionary response. Declining productivity, widespread osprey nest failures, and continuing concerns regarding the Chesapeake Bay striped bass population are not isolated issues. They are reasons to examine carefully whether we are removing too much forage from the Bay at the wrong time.

Menhaden are a foundational forage species. They feed an extraordinary range of predators, including striped bass and osprey. Yet the reduction fishery can remove **more than 100 million pounds of menhaden from Chesapeake Bay under the existing annual cap.** When a substantial portion of that harvest is concentrated into an intense summer fishing window, the issue is not simply how many fish are removed annually. **It is when and where those fish are removed.**

A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource.

The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. **One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users.**

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy.

The Chesapeake Bay is not simply a location on a fisheries-management map. It is a complex and interconnected ecosystem, and menhaden are one of its essential links.

We should not wait for further deterioration before taking action.

As someone who lives here, sails these waters, dives in them, and cares deeply about the wildlife that depends upon them, I believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.

Thank you for considering my comments.

Sincerely,

Barbara Bershon
St. Mary's County, Maryland

Subject: [External] Osprey in NJ

To Whom It May Concern,

My family and I live bayfront on Little Egg Harbor Bay in NJ. We have been watching osprey nests for a number of years on the channel marker just outside our back yard.

It was heartbreaking last year to see the parents fail to fledge any chicks from their nest. This year they do have fledgelings, but the competition for food and what they are able to catch is so distressing. We are watching them bring baby fluke back to the nest daily - but no bunker/menhanden - which is a much more substantial meal for them. Larger osprey constantly try to steal the fish that are being brought back to the nest by the parents - these poor birds are literally starving.

We implore you to drastically reduce the amount of commercial fishing allowed for menhaden. They are the backbone of the ocean - not only the osprey need them, but many other species do as well.

Please, please, please protect this resource which is so crucial to so many species, as well as fishermen and bait shops up and down the Atlantic Coast. Please dramatically reduce the amount of menhaden that is able to be taken and limit the timing of when they can be taken so that the menhaden can repopulate and flourish and in turn the osprey and other species that need them can flourish again, as well. Nature is telling us clearly that we need to stop this overharvesting of menhaden for commercial gain - please heed the warning and drastically reduce the amount of menhaden that the commercial fishermen can take.

Thank you for your consideration,

Paula Brennan

Comment
The food chain for Chesapeake fish and foul begins with menhaden. The current reduction scale is not supportable. Chesapeake fish and foul are suffering because of the depletion. At the very least, a 50% reduction will provide an opportunity for the menhaden stock to begin recovering.

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I strongly support reducing the Chesapeake Bay reduction-fishery cap by **50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

I have lived in St. Mary's County since 2008 and am lucky enough to have an osprey nest just off my pier. We used to have two to three chicks annually fledge and migrate at the end of the season. Now, we are lucky to have one chick and the last three years they have all starved before fledging.

The evidence points to a decline in the number of menhaden that the ospreys, striped bass and other marine life in the Chesapeake watershed depend upon for their survival.

It is both when and where those fish are removed that matter. A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource.

The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. **One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users.**

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just one Virginia based fishing company.

The Chesapeake Bay is not simply a location on a fisheries management map. It is a complex and interconnected ecosystem, and menhaden are one of its essential links.

We should not wait for further deterioration before taking action. There is no time for additional five-year studies to delay the decision. The severe drop in nesting pairs and the lack of surviving chicks will not replenish the specicies enough to survive that long.

As someone who lives here, fishes and sails these waters, swims in them, and cares deeply about the wildlife that depends upon them, I believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.

Thank you for your consideration.

Sincerely,

Chris Allen

PUBLIC COMMENT ON ATLANTIC MENHADEN DRAFT ADDENDUM II

Support the Strongest Chesapeake Bay Protections Now - and Begin Moving the Industrial Reduction Fishery Out of Virginia State Waters

Submitted to the Atlantic States Marine Fisheries Commission
Atlantic Menhaden Management Board
October 2026

Submitted by: Debbie Campbell

Stakeholder interest: Bay-adjacent property owner in Northampton County, Virginia; Maryland property owner; recreational angler and conservation advocate; Editor and a founder of Menhaden Little Fish - Big Deal!; member of SMRFO and the Virginia Saltwater Sportfishing Association (VSSA).

Position: I support the most protective options in Draft Addendum II, including the maximum 50 percent reduction in the Chesapeake Bay reduction-fishery cap. I believe the Addendum should be treated as an important interim step toward ending industrial reduction fishing in Virginia state waters.

REQUESTED ACTION

I strongly support Draft Addendum II and urge the Atlantic Menhaden Management Board to adopt the most protective alternatives available for Chesapeake Bay.

At minimum, I support the maximum 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons. I also support the strongest available measures to distribute harvest more evenly through the season and to prevent future coastwide Total Allowable Catch increases from automatically increasing industrial harvest pressure inside Chesapeake Bay.

I support the Addendum because precaution is warranted now. But I do not regard a 50 percent cap reduction as the endpoint. Based on the scientific record, the unresolved Chesapeake-specific questions, the ecological warning signs, and the experience of communities along the Bay, I continue to believe that industrial reduction fishing should ultimately be removed from Virginia state waters and conducted in ocean waters instead.

WHY THIS MATTERS TO ME

My interest in this issue is both personal and longstanding. I own Bay-adjacent property in Northampton County, Virginia, and property in Maryland, and I have watched and used Chesapeake waters for years. I am also the Editor and a founder of Menhaden Little Fish - Big Deal!, a member of SMRFO and the Virginia Saltwater Sportfishing Association (VSSA), a recreational angler, and a conservation advocate. Through this work, I have sought to increase public awareness of menhaden, their importance to the Chesapeake ecosystem, and the management issues surrounding the fishery.

Fishing is one of the ways I teach children conservation - respect for the resource, responsible angling, and proper catch-and-release practices. I want them to inherit a Chesapeake Bay in which conservation is something they can experience, not simply something they are told once existed.

The industrial menhaden operations along this shoreline have affected me greatly. Images of menhaden fish kills have stayed with me. I have watched the birds that drew me to this place and have seen some of those familiar sights diminish or disappear. These experiences are not substitutes for scientific evidence, and I do not offer them as such. They are why the scientific questions discussed in this comment are not abstract to me.

When I fish with children, I teach them that conservation means taking responsibility for what we remove from the water and leaving enough behind for the ecosystem and for those who come after us. I believe our fisheries-management institutions should operate according to the same principle.

1. A HEALTHY COASTWIDE STOCK DOES NOT ANSWER THE CHESAPEAKE BAY QUESTION

The latest Atlantic menhaden assessment is important and should be respected: coastwide, the stock is not overfished and overfishing is not occurring.

But ASMFC itself cautions that this status applies to the Atlantic coast as a whole and that, because of the assessment methodology, no inferences can be made at a smaller regional scale such as Chesapeake Bay.

That limitation is central. The relevant management question is not simply whether Atlantic menhaden are abundant from Florida to Maine. It is whether Chesapeake Bay contains enough menhaden, in the right places and seasons, to support predators and other fisheries while a concentrated industrial reduction fishery operates inside the estuary.

ASMFC created the Bay cap as a precautionary response to localized-depletion concerns. Draft Addendum II itself now responds to concerns about concentrated reduction-fishery effort, effects on Bay bait fisheries, and potential ecological impacts. A coastwide finding of sustainability therefore should not be treated as proof that localized ecological risk is absent.

2. THE SCIENTIFIC UNCERTAINTY SUPPORTS PRECAUTION, NOT DELAY

ASMFC's Chesapeake Bay Work Group was directed to evaluate additional precautionary management, including time and area protections for predatory birds and fish. The Work Group did not determine whether the Bay has an adequate supply of menhaden to meet predator demand; instead, it identified management options and research needs.

The broader record underscores how much Chesapeake-specific information remains unresolved. Virginia Institute of Marine Science scientists have characterized important information concerning menhaden abundance and ecological effects within Chesapeake Bay as "woefully inadequate." At an April 2026 Virginia Marine Resources Commission hearing, this characterization was explained in the context of how far scientists remain from being able to quantify some of the Chesapeake-specific questions managers are being asked to answer.

Even representatives of the reduction fishery have acknowledged the need for additional research. At that same hearing, Ocean Harvesters CEO Monty Deihl/Diehl described cooperative tagging research with VIMS intended, in part, to help researchers determine what percentage of the menhaden present in Chesapeake Bay is being harvested by the fleet. He acknowledged that this work is a major undertaking that will take time.

That is precisely why action is justified. Where managers cannot yet quantify Bay-specific abundance, movement, predator demand, or localized effects with confidence, maintaining the existing level of concentrated industrial removal is not a scientifically neutral choice. It places the risk of uncertainty on the ecosystem.

The Commission should continue and accelerate tagging, abundance, migration, predator-demand, and spatial research. But "wait for more science" should not mean maintaining industrial-scale extraction until ecological damage can be proven conclusively after the fact.

3. OSPREY RESEARCH IS AN ECOLOGICAL WARNING THAT DESERVES WEIGHT

Recent peer-reviewed research from the Center for Conservation Biology and collaborators has documented serious reproductive deficits and food stress among Chesapeake Bay ospreys in high-salinity waters.

In the 2024 breeding season, all high-salinity study areas examined functioned as demographic sinks, while low-salinity areas functioned as demographic sources. The researchers concluded that several factors may influence productivity but identified reduced Atlantic menhaden availability as a primary driver of poor reproduction in high-salinity waters.

Earlier work in Mobjack Bay documented declining menhaden delivery to nests, declining reproductive performance, and increased food stress. Experimental supplementation with menhaden improved reproductive output.

These studies do not establish that commercial harvest alone caused the decline, and I do not claim that they do. They do establish that menhaden availability can be biologically consequential for Chesapeake predators.

The absence of proof that the reduction fishery is the sole cause of ecological harm is not evidence that concentrated harvest has no ecological consequence. That distinction should matter in precautionary management.

4. CONCENTRATED FISHING AND THE BAY ENTRANCE REMAIN UNRESOLVED MANAGEMENT CONCERNS

ASMFC's Work Group examined concerns that concentrated purse-seine sets near the mouth of Chesapeake Bay could function as an "intercept" fishery.

The available information did not establish that such an effect is occurring, and the report also discussed observations that could point the other way. That uncertainty should be stated plainly.

But the issue remains unresolved because the necessary movement and biomass information is incomplete. The appropriate response is not to convert uncertainty into an assumption of no effect. It is to reduce risk while obtaining the data needed to resolve the question.

Industry representatives have also explained that Chesapeake Bay provides protected operating conditions when offshore seas make purse-seine fishing difficult or unsafe. That is a legitimate operational and economic concern. It is not, however, an ecological justification for maintaining an industrial reduction fishery inside an estuary when the local forage consequences remain inadequately resolved.

5. ECONOMIC ANALYSIS MUST COUNT THE VALUE OF FORAGE LEFT IN THE ECOSYSTEM

The reduction fishery provides jobs, products, and economic activity. Those interests deserve consideration. But they are not the only economic interests connected to menhaden.

Dr. Ellen Pikitch and coauthors evaluated the global economic contribution of forage fish. Their peer-reviewed analysis estimated approximately $5.6 billion annually in direct global forage-fish catch value and approximately $11.3 billion in commercial fisheries supported by forage fish as prey.

The authors also noted that their estimate did not monetize recreational fisheries or non-fishery uses, so it did not capture the full economic contribution of forage fish.

These are global estimates, not a Chesapeake Bay valuation. They should not be presented as dollar values for Virginia or Chesapeake menhaden. Their relevance is the economic principle they demonstrate: a forage fish can generate value both when harvested directly and when left in the water to support predators, commercial and recreational fisheries, wildlife, tourism, and other ecosystem services.

ASMFC should therefore consider both sides of the economic ledger rather than measuring the consequences of conservation only as foregone reduction-fishery landings.

6. NORTHAMPTON COUNTY HAS DOCUMENTED THE LOCAL COMMUNITY INTEREST

On January 9, 2024, the Northampton County Board of Supervisors adopted a resolution stating the County's position that industrial Atlantic menhaden fishing should be prohibited within Chesapeake Bay and within three miles of Commonwealth lands, and requesting that Virginia agencies establish and enforce such a prohibition.

The County's published explanation cites concerns involving sport fishing and charter businesses, tourism, fish spills and fish kills, private and public property, and the concentration of purse-seine activity near Northampton County.

This resolution does not substitute for ASMFC's scientific process. It does demonstrate that the economic and quality-of-life effects perceived by a directly affected Virginia locality extend beyond the reduction industry.

7. ADDITIONAL STAKEHOLDER CONTEXT: WILLIAM McKEEVER'S DOCUMENTARY

I also encourage interested Board members and members of the public to view William McKeever's documentary, The Biggest Little Fish You've Never Seen.

The film presents an advocacy perspective on Chesapeake menhaden, industrial reduction fishing, wildlife, recreational fishing, and affected communities.

I do not offer the film as a scientific study, and its claims should be evaluated against the primary scientific and management record. Its value here is as stakeholder and educational context: it illustrates why this fishery has become a deeply felt Chesapeake conservation issue.

8. DRAFT ADDENDUM II SHOULD BE AN INTERIM STEP, NOT THE ENDPOINT

The Commission does not need to conclude that localized depletion has been proven in order to act cautiously.

The existing coastwide assessment cannot demonstrate that localized depletion is not occurring in Chesapeake Bay, and important Bay-specific questions remain unresolved.

I recognize that workers, vessels, processors, and communities depend economically on the reduction fishery. I do not dismiss those consequences.

But there are other people who depend upon this Bay as well - watermen, charter captains, recreational anglers, property owners, tourism businesses, families, and future generations.

For that reason, I support the strongest protections available in Draft Addendum II now, while urging managers to begin considering a longer-term framework under which industrial reduction fishing is removed from Virginia state waters.

REQUESTED BOARD ACTIONS

1. Adopt the maximum 50 percent reduction in the Chesapeake Bay reduction-fishery cap, reducing the cap from 51,000 metric tons to 25,500 metric tons.
2. Adopt the strongest available seasonal and quota-period measures to reduce concentrated harvest during ecologically important portions of the fishing season.
3. Choose the option that prevents future increases in the coastwide TAC from automatically increasing industrial harvest pressure inside Chesapeake Bay.
4. Continue and accelerate Chesapeake-specific research on menhaden abundance, movement, predator demand, localized depletion, and the ecological consequences of concentrated harvest.
5. Treat these measures as interim protections and begin evaluating a management framework that ultimately removes industrial reduction fishing from Virginia state waters.

CONCLUSION

Menhaden are both a fishery resource and a foundational forage species.

The Commission's responsibility is therefore broader than maximizing sustainable coastwide removals. It must also consider whether management adequately protects the ecological functions menhaden provide in places such as Chesapeake Bay.

Please adopt the strongest protections available under Draft Addendum II. Continue the science. Reduce the risk while that science is being developed. And begin the process of moving the industrial reduction fishery out of Virginia state waters.

That approach would recognize both what the science tells us and, just as importantly, what the current science still cannot tell us about Chesapeake Bay.

James,
Attached is the Northampton County resolution that I mentioned during the hearing/meeting. I will send the economic analysis information separately. I request that this be entered into the public record, and to be considered and referenced in discussions and considerations of economic impact of industrial menhaden reduction fishing.
Regards.
Debbie

RESOLUTION

A RESOLUTION OF THE NORTHAMPTON COUNTY BOARD OF SUPERVISORS APPROVING THE COUNTY'S POSITION THAT INDUSTRIAL ATLANTIC MENHADEN FISHING SHOULD BE PROHIBITED WITHIN THE WATERS OF THE CHESAPEAKE BAY AND THREE MILES OF ALL LANDS OF THE COMMONWEALTH AND REQUESTING THAT THE VIRGINIA MARINE RESOURCE COMMISSION AND STATE AGENCIES LEGALLY ESTABLISH AND ENFORCE A PROHIBITION OF THE INDUSTRIAL ATLANTIC MENHADEN FISHERY WITHIN THE WATERS OF THE CHESAPEAKE BAY AND WITHIN THREE MILES OF ANY LANDS OF THE COMMONWEALTH.

WHEREAS, Atlantic menhaden are an ecologically essential keystone species of the Chesapeake Bay ecosystem that support commercially and recreationally important fisheries, maintain water quality by filtering nutrients from the water, and provide essential nutrients for numerous species in the bay food chain; and

WHEREAS, industrial menhaden fishing in the Chesapeake Bay negatively impacts Northampton County by reducing the stock of menhaden available to support important fisheries and wildlife, reducing the populations of recreational and commercial fish species caught in purse seine nets as by-catch, and reducing the population of predator species such as osprey, dolphins, sharks, humpback whales, striped bass, redfish, weakfish, and speckled trout, all of which contribute to the general and tourism economy of Northampton County; and

WHEREAS, industrial menhaden fishing operates on a tactical level where they use spotter airplanes that can quickly cover the entire Chesapeake Bay in a matter of hours, the planes then locate schools of menhaden by air, and then quickly dispatch their boat fleet to extract schools of menhaden from the Chesapeake Bay with purse seine nets. By design, these highly efficient industrial extraction methods cause localized depletion of Atlantic menhaden in the Chesapeake Bay and it is not known how long it may take the Chesapeake Bay ecosystem to recover from excessive depletion of biomass, and whether a full recovery is even possible; and

WHEREAS, the Virginia Secretary of Natural Resources, Virginia Marine Resources Commission, and members of the Atlantic Menhaden Technical Committee of the Atlantic States Marine Fisheries Commission can not provide Northampton County scientific assurance that the spatial or seasonal stock of menhaden in the Chesapeake Bay is healthy, and the impact of localized depletion due to industrialized Atlantic menhaden fishing techniques in the Chesapeake Bay (VIMS et al. 2023); and

WHEREAS, both the Virginia Institute of Marine Science and the Maryland Department of Natural Resources published record low striped bass recruitment numbers for 2023, this is the fifth consecutive year of juvenile striped bass numbers being below the average and the second lowest striped bass index ever recorded since 1957 (MDNR et al. 2023, Small et al. 2023, VIMS et al. 2023); and

Whereas, research suggests industrial reduction menhaden fishing in the Chesapeake Bay could be responsible for a decline in striped bass (Buchheister et al. 2017, TRCP et al. 2019). The Virginia Institute of Marine Science linked striped bass starvation to a decline of forage food in the Chesapeake Bay, and starvation as a cause for predisposing fish to Mycobacteriosis, locally referred to as fish wasting disease (Cardinal et al. 2001); and

WHEREAS, the Virginia Institute of Marine Science recorded industrial menhaden trawlers catching striped bass in their purse nets in the Chesapeake Bay, the average size of the striped bass caught by these industrial menhaden trawlers was over 34 inches, well above the 31 inches established by the ASMFC, suggesting that the striped bass being caught by industrial menhaden trawlers as by-catch are of size to be important breeders for striped bass recovery (Kirkley et al. 1995, ASMF et al. 2023); and

WHEREAS, in 2023, the Center for Conservation at the College of William and Mary published record low osprey chick recruitment numbers in the Chesapeake Bay, the lowest recruitment numbers since 1970 as a result of starvation, a reproduction number that is lower than what occurred at any time during the DDT era and a much lower rate than is sustainable for the Bay population of Osprey (Hafner et al. 2023); and

WHEREAS, industrial menhaden fishing has caused fish kills and fish spills that have impacted public beaches, private property, and public health in Northampton County; and

WHEREAS, industrial menhaden fishing adversely impacts the economic well-being of Northampton County by disrupting the health of our local commercial industry; and

WHEREAS, industrial menhaden fishing adversely impacts the economic well-being of Northampton County by disrupting our local sport fishing industry; and

WHEREAS, industrial menhaden fishing adversely impacts the economic well-being of Northampton County by disrupting our local tourism industry, due to the adverse effects of fish spills, fish kills, the persistent rotting odor of fish spills and fish kills, and reduced sport fishing; and

WHEREAS, all other states on the Atlantic Coast have removed industrial menhaden fishing from their bays and state waters, and have now recorded positive ecological and economic responses in doing so (Main et al. 2023); and

NOW THEREFORE BE IT RESOLVED that the Northampton County Board of Supervisors, this 9th day of January, 2024, establishes the County's position that industrial

Atlantic menhaden reduction fishing should be prohibited within the waters of the Chesapeake Bay and three miles of all lands on the Commonwealth and requests that the Virginia Marine Resources Commission and state agencies legally establish and enforce a prohibition of the industrial Atlantic menhaden reduction fishery within the waters of the Chesapeake Bay and within three miles of any lands of the Commonwealth.

Northampton County Board of Supervisors

The undersigned Clerk of the Northampton County Board of Supervisors hereby certifies that the above is a true copy of a resolution adopted by the Northampton County Board of Supervisors on January 9, 2024.

Clerk, Northampton County Board of Supervisors

little fish
BIG IMPACT

Fact Sheet

The Economic Value of Forage Fish

From *Little Fish, Big Impact*, a report from the Lenfest Forage Fish Task Force

On April 3, 2012, the Lenfest Forage Fish Task Force released *Little Fish, Big Impact,* the most comprehensive global analysis to date of the biology and management of forage fish. One of its significant contributions is the first global estimate of the total economic value of forage fish to commercial fisheries, including their indirect, "supportive" value when left in the ocean.

The Task Force used 56 food web models from the scientific literature to estimate (1) the volume of forage fish catch and (2) the contribution of forage fish as prey to the catch of other commercial fish, such as tuna, salmon, and cod. By combining these results with a database of fish prices, the Task Force calculated both "direct value" from catch of forage fish and "supportive value"—their value when left in the water as food for commercially fished predators. The Task Force found that:

- Globally, forage fish are twice as valuable in the water as in the net. The report estimates that the supportive value of forage fish left in the water as food for commercially valuable predators is $11.3 billion globally (in 2006 dollars), compared to a direct catch value of $5.6 billion.[1] Supportive value is greater than direct value in 30 of the 56 ecosystem models studied.[2]

1. The estimate of supportive value is conservative because it does not include predators with no commercial value as catch, such as seabirds and marine mammals. It also excludes the economic value of recreational fisheries, ecotourism, and ecosystem services such as water filtration.
2. The Task Force used published models as a relatively rapid way to assess the global aggregate value of forage fish, but these models only provide a snapshot of direct and supportive value in each ecosystem. These values would change along with any change in prices or fishing effort.

Economic importance of forage fish

TOTAL $16.9 BILLION

Direct value of commercial forage catch

$5.6 billion

Supportive value of forage fish to other commercial catch

$11.3 billion

WHAT ARE FORAGE FISH?

Forage fish are small to medium-sized species that include anchovies, herring, menhaden, and sardines. They are food for numerous marine predators, including commercially important fish like cod, salmon, and tuna.

- Forage fish direct and supportive values vary tremendously across the globe. The Task Force found some patterns across latitudes and ecosystem types. For example, the direct value of forage fish is greatest on average near the equator and lowest at high latitudes. The reverse is true for supportive value, which is greatest at high latitudes and lowest near the equator, on average.[3] (The Task Force did not investigate possible explanations for these trends.)

- Managers can identify trade-offs. The Task Force's analysis provides a method for identifying the economic value of forage fish, both as a commodity and as prey for other commercial fisheries. Managers may use or expand upon this approach in specific ecosystems to examine potential trade-offs between harvesting forage fish and keeping them in the ocean.

- Management should focus on predators. Because forage fish tend to be more valuable as prey than as direct catch, the Task Force recommends that managers focus on the needs of predators when making decisions about forage fisheries. In addition to its economic analysis, the Task Force analyzed strategies to help ensure forage fishing does not unduly deplete predator populations. Based on this analysis, the Task Force recommends cutting catch rates by at least half in most ecosystems and doubling the minimum population size of forage fish, relative to conventional management.[4]

3. In order to compare across ecosystems, the report gives forage fish value in 2006 dollars per square kilometer per year ($/km^2/yr). Average direct value was about $880/ km^2/yr near the equator and about $166/ km^2/yr for high-latitude ecosystems. Average supportive value was about $153/ km^2/yr near the equator and about $631/ km^2/yr for high-latitude ecosystems.
4. The Task Force did not make ecosystem-specific recommendations. Rather, it made a set of recommendations based on the level of information available about the fishery and ecosystem.

What the Menhaden Debate Is Really About

A point-by-point rebuttal to the American Small Pelagics Network's case against additional Chesapeake Bay protections

By: Debbie Campbell

The question is not whether Atlantic menhaden are healthy coastwide. The question is whether a coastwide assessment can establish that Chesapeake Bay contains enough forage, in the right places and seasons, while a concentrated industrial reduction fishery operates inside the estuary and at its entrance.

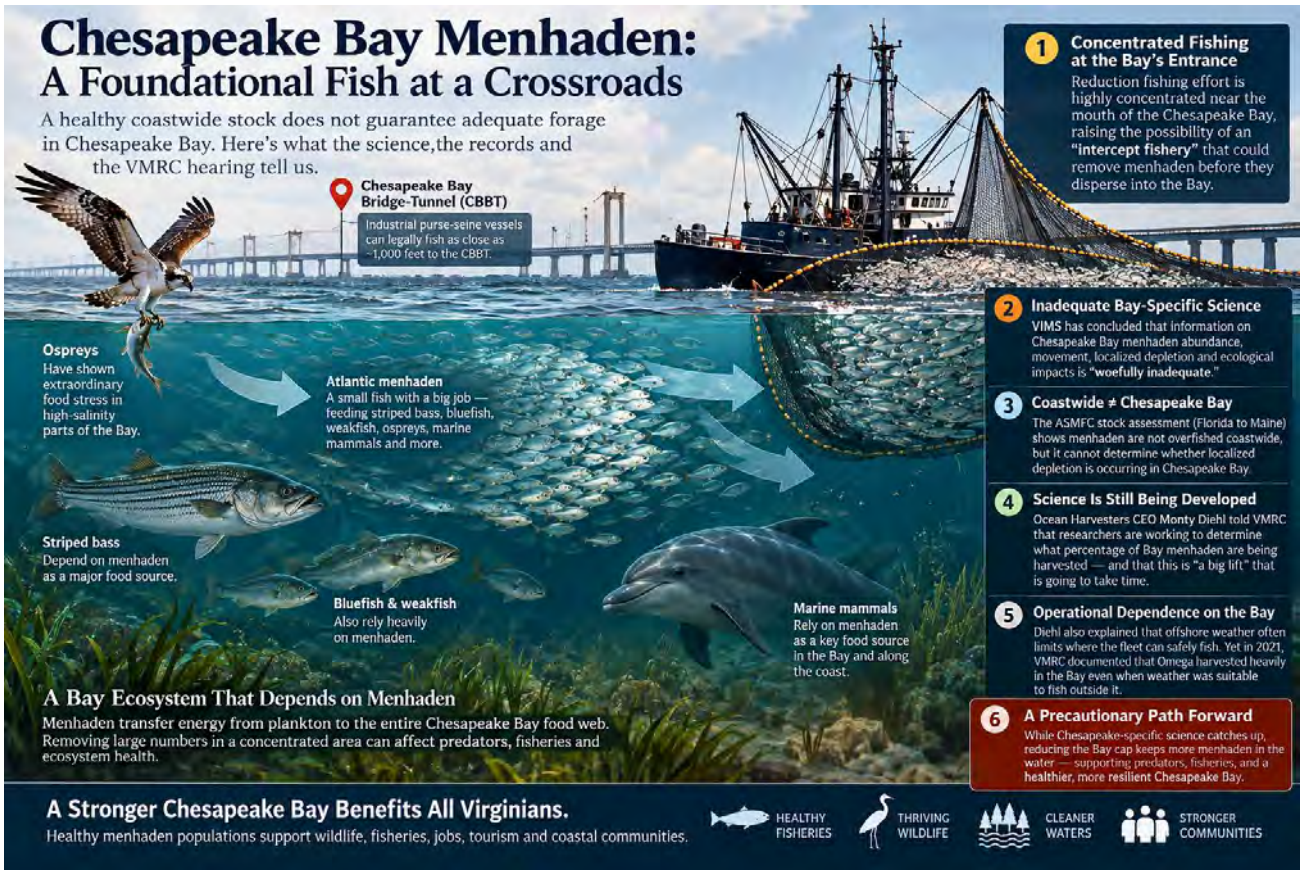

Illustration: the management problem is spatial. Coastwide stock status does not answer Bay-scale forage questions.

This response follows the argument advanced by the American Small Pelagics Network (ASPN) in its October 2026 public commentary and related reporting: stock status, ecological reference points, osprey science, striped bass, economics, corporate ownership, ongoing research, and the Chesapeake Bay cap. Where ASPN is correct, this rebuttal says so. Where its framing outruns what the evidence can establish, the distinction matters.

The Core Problem With ASPN's Argument

ASPN repeatedly answers a local ecological question with coastwide evidence. That is the central weakness in its case. The 2025 Atlantic menhaden assessment is important and reassuring at the stock-wide scale: the species is not overfished and overfishing is not occurring. But the Chesapeake Bay controversy is not a claim that the coastwide stock is collapsing. It is a question about local abundance, distribution, migration, predator access and concentrated removals inside one of the Atlantic coast's most important estuaries.

ASMFC itself has preserved a separate Chesapeake Bay reduction-fishery cap precisely because localized depletion has long been a management concern. Draft Addendum II now considers options including a reduction of that cap by as much as 50 percent. The Commission's own work acknowledges that available information is insufficient to comprehensively characterize Bay-wide abundance, distribution and fishing effects. That uncertainty does not prove harm. It also does not prove safety.

A sound rebuttal therefore should not claim that commercial harvest has been proved to cause every osprey, striped-bass or bait-fishery problem. The stronger scientific case is narrower: substantial ecological warning signs exist; industrial effort is concentrated; the Bay-specific science needed to quantify the risk remains incomplete; and precaution is a legitimate management response while that science catches up.

1. "The Stock Is Healthy, So Further Bay Restrictions Are Not Scientifically Justified"

> **ASPN'S CLAIM: The 2025 Atlantic menhaden stock assessment found the stock not overfished and not experiencing overfishing. ASPN presents that result as a major reason to resist additional Chesapeake Bay restrictions.**

REBUTTAL

The stock-status statement is true. The inference ASPN asks readers to draw from it is not.

A coastwide assessment estimates the status of a single stock unit spanning a vast geographic range. It does not measure how many adult menhaden are present in Chesapeake Bay at a given time, how schools move through the Bay mouth, how long they remain available to local predators, or whether intense harvest in a particular area can create localized depletion.

VMRC staff made this scale explicit at the April 21, 2026 hearing, describing the single-species assessment as generating estimates for the coastwide stock as a single unit from Florida to Maine. That is the appropriate scale for coastwide overfishing status. It is not a Chesapeake Bay forage assessment.

ASMFC's own public materials likewise caution against converting coastwide status into a local conclusion. The Bay cap exists as a separate management tool because localized depletion is a different question from coastwide stock collapse.

> **A healthy Atlantic stock and a locally stressed Chesapeake forage base can exist at the same time. One finding does not disprove the other.**

2. "Ecological Reference Points Already Protect Predators"

> **ASPN'S CLAIM: ASPN argues that ASMFC's ecological reference points already account for predator needs and emphasizes that the adopted 2026 catch level had a modeled zero-percent probability of exceeding the ecological overfishing threshold.**

REBUTTAL

Ecological reference points are an important advance and should be defended. But ASPN's presentation blurs two distinctions: threshold versus target, and coastwide ecosystem modeling versus local forage sufficiency.

ASMFC reduced the 2026 coastwide total allowable catch by 20 percent after the 2025 assessment showed fishing mortality above the ERP target and fecundity below the ecological target. The fact that the adopted catch level was modeled below the overfishing threshold does not mean the stock was at the preferred ecological target. A threshold is the boundary managers seek not to cross; the target is the management objective.

ASMFC's 2025 ERP analysis shows why the ecological target matters. The Board reduced the coastwide total allowable catch (TAC) from 233,550 metric tons in 2023–2025 to 186,840 metric tons for 2026, a 20 percent cut. Even at that level, projections indicated a 100 percent probability of fishing mortality exceeding the ERP target, though a zero percent probability of exceeding the overfishing threshold. ASMFC stated that a reduction of 50 percent or more from the prior TAC would be needed to lower the probability of exceeding the ERP fishing-mortality target. A 50 percent reduction from 233,550 metric tons would mean 116,775 metric tons—37.5 percent below the 2026 TAC, or roughly another 40 percent. These results reflect an ecosystem target designed around forage demands of striped bass; they do not establish that any one TAC change alone will recover striped bass. Nor does the coastwide ERP model establish a Chesapeake-specific quota. Nonetheless, the scale of the coastwide ecological gap strengthens the precautionary case for a significant reduction in concentrated Bay harvest while Bay-specific research is developed. (ASMFC, October 2025 TAC announcement and Atlantic Menhaden FAQ.)

Nor does the ERP framework certify that every predator in every region has adequate prey. The model is built around specified predator-prey relationships, with striped bass playing a central role. It does not establish an osprey forage requirement for high-salinity Chesapeake waters, nor does it calculate whether menhaden are sufficiently available near individual nesting areas or throughout the Bay.

> **The correct conclusion is that ERPs improve coastwide management - not that they eliminate the need to manage spatially concentrated forage risk inside Chesapeake Bay.**

3. "Osprey Studies Do Not Prove the Reduction Fishery Caused the Decline"

> **ASPN'S CLAIM: ASPN notes that Chesapeake osprey researchers identified food stress but did not design their studies to prove that commercial menhaden harvest caused the reproductive decline. It also points to osprey problems in other regions.**

REBUTTAL

This is partly correct and should be conceded. The published Chesapeake studies do not establish that commercial harvest alone caused poor osprey reproduction. A credible rebuttal should not say otherwise.

But that concession does not make the osprey evidence irrelevant. Recent Chesapeake research has documented declining reproductive performance, reduced menhaden deliveries to nests, brood reduction and nest failure in high-salinity areas. A food-supplementation experiment improved reproductive performance, directly supporting food limitation as an important mechanism. A 2026 Bay-wide study found the high-salinity study areas functioning as demographic sinks and identified reduced Atlantic menhaden availability as a primary driver of poor reproduction there.

The Center for Conservation Biology's 2026 reporting described the Bay's osprey breeding performance as the worst in its long-term record, with none of the monitored areas above 5 ppt salinity reaching productivity needed for population maintenance. Researchers also reported major declines in menhaden delivery to nests in some areas and a lower-energy diet as ospreys shifted to alternative prey.

Evidence of osprey problems elsewhere does not negate the Chesapeake mechanism. Different populations can experience food limitation for different reasons. The management question is whether managers should ignore a strong local forage signal until a study isolates one human activity as the sole cause.

> **"The fishery has not been proved to be the sole cause" is scientifically defensible. "Therefore local menhaden availability is adequate" is not.**

4. "Managers Should Wait for the Ongoing Chesapeake Studies"

ASPN'S CLAIM: ASPN urges managers to wait for several ongoing, publicly funded Chesapeake studies before imposing additional restrictions.

REBUTTAL

This sounds cautious, but it treats the status quo as if it were scientifically neutral. It is not. Continuing concentrated removals at the existing cap while waiting for better data is itself a risk-allocation decision.

The most important evidence here comes from Virginia's own scientific and regulatory record. VIMS characterized information on Chesapeake menhaden abundance, movement between the Bay and shelf, localized depletion from fishing, and ecological impacts of purse seining as "woefully inadequate." At the April 2026 VMRC hearing, VIMS scientific adviser Lyle Varnell explained that, compared with other species, managers are "way behind the curve" in determining the biomass needed to support the Bay food web.

Ocean Harvesters CEO Monty Diehl's testimony underscored the same information gap from the industry side. While opposing a moratorium, he described tagging research intended in part to determine what percentage of menhaden in the Bay the fishery actually harvests, calling the work a major undertaking that will take time.

That creates a straightforward management problem: if the science is not yet capable of measuring local abundance, movement and harvest fraction adequately, the absence of a demonstrated localized-depletion signal cannot be treated as proof that localized depletion is not occurring.

The precautionary question is therefore not whether research should continue - it absolutely should. It is who bears the risk while managers wait. A lower cap leaves more forage in the ecosystem while the studies proceed. Maintaining the current cap places more of the uncertainty on predators, competing fisheries and the Bay food web.

5. "The Bay Cap Was Political and Has Never Been Scientifically Quantified"

ASPN'S CLAIM: ASPN points to the history of the Chesapeake Bay cap and earlier ASMFC statements that the cap was not derived from a scientifically quantified local harvest threshold.

REBUTTAL

That history is relevant. The current cap is not the output of a Bay-specific biomass model that calculates a precise biologically necessary tonnage. But this does not make the cap scientifically meaningless, nor does it follow that a precautionary reduction lacks a scientific rationale.

The cap's purpose has always been different from a coastwide overfishing limit: it is a risk-management measure intended to constrain concentrated reduction harvest in the face of concern about localized depletion. Precautionary limits are often used precisely where managers cannot calculate a perfect local threshold.

More importantly, management conditions have changed since the older statements ASPN cites. Draft Addendum II is being considered against a current record that includes concentrated summer reduction effort, concerns about declining Bay pound-net harvest and catch per unit effort, new predator research, and explicit recognition that Bay-specific abundance and movement information remains inadequate.

A historical statement that managers could not quantify a biological benefit from the cap under conditions in 2012 is not a scientific finding that no localized risk can exist in 2026.

6. "There Is No Proof of an Intercept Fishery at the Bay Mouth"

ASPN'S CLAIM: Industry advocates dispute the idea that the reduction fleet forms a 'gauntlet' that prevents menhaden from reaching the upper Bay, noting that existing analyses do not establish a simple cause-and-effect relationship.

REBUTTAL

Again, the narrow proposition is fair: the available evidence does not prove that purse-seine sets near the Bay mouth systematically block menhaden from reaching Maryland. The rebuttal should not claim otherwise.

But ASMFC's Chesapeake Bay work group examined this exact concern because reduction-fishery effort is substantially concentrated near the mouth of the Bay. The group identified migration and biomass information needed to determine whether concentrated sets can function as an intercept fishery. In other words, the question is unresolved, not disproved.

That matters because the fleet is permitted to operate extremely close to the Chesapeake Bay Bridge-Tunnel, at the estuary's principal marine gateway. Concentrated industrial removal at an entrance through which forage fish migrate presents a different ecological-risk profile from dispersed coastwide harvest. If managers cannot yet quantify migration timing, local biomass, predator demand or the fraction of Bay fish removed, a narrow buffer does little to resolve the underlying uncertainty.

The fleet's operational dependence on protected Bay waters adds context. At the April 2026 VMRC hearing, Diehl explained that offshore sea conditions often make purse-boat operations unsafe and argued that losing Bay access could threaten the business. That economic reality deserves consideration - but it is not an ecological reason to maximize Bay harvest.

A September 8, 2021 letter from then-VMRC Commissioner Steven G. Bowman to "Mr. Montgomery Diehl, Omega Protein" is particularly revealing. Bowman wrote that Omega had already taken 38,390 metric tons - 75.3 percent of the Bay cap - and criticized the fact that the harvest occurred despite weather suitable for fishing outside the Bay. The point is not that offshore weather never constrains the fleet. It is that Bay harvest cannot be explained solely as a rough-weather necessity.

The scientifically defensible position is not "the intercept effect has been proved." It is "the intercept risk is credible, spatially concentrated and unresolved - exactly the kind of uncertainty for which a precautionary cap exists."

7. "Menhaden Restrictions Will Not Rebuild Striped Bass"

ASPN'S CLAIM: ASPN notes that eliminating menhaden fishing alone would not rebuild striped bass and emphasizes that recreational harvest and release mortality account for a large share of striped-bass removals.

REBUTTAL

Both points can be true without resolving the forage issue. Striped bass face multiple interacting pressures. Direct fishing mortality, recruitment, habitat conditions, disease, temperature and prey availability do not cancel one another out.

No credible case for reducing the Chesapeake Bay cap requires claiming that menhaden harvest is the sole cause of striped-bass decline or that menhaden conservation alone will rebuild the stock. The question is whether a stressed predator population benefits from maintaining abundant, accessible forage in a major nursery and feeding estuary.

ASPN also cites analyses finding sampled striped bass in generally acceptable body condition. That is useful evidence about the fish examined. It does not measure menhaden availability throughout Chesapeake Bay, nor does it establish that forage is spatially sufficient for every predator or life stage.

"Menhaden conservation alone will not rebuild striped bass" is not a rebuttal to forage management. It is a reminder that ecosystem management must address more than one pressure at a time.

8. "Menhaden Are Not Necessarily Worth More Left in the Water"

ASPN'S CLAIM: ASPN challenges claims that menhaden are categorically worth more as forage than when harvested and emphasizes jobs, wages, bait, fishmeal, fish oil and other products created by the fishery.

REBUTTAL

The reduction fishery unquestionably creates economic value and supports real workers and families. A serious conservation argument should acknowledge that rather than treating Reedville jobs as disposable.

But the reverse simplification is equally problematic. Economic value is not created only when a menhaden crosses a dock. Menhaden left in the ecosystem support recreational and commercial predator fisheries, bait availability, wildlife viewing, tourism, nutrient and food-web functions, future spawning biomass and ecological resilience.

The correct economic question is therefore allocation: how should a public forage resource be divided among direct industrial harvest, bait fisheries, predators and ecosystem functions? A sales figure for processed menhaden products cannot answer that question by itself.

A temporary or precautionary cap reduction also is not equivalent to eliminating the fishery. Draft Addendum II is considering a range of options, including reductions short of closure. Economic impacts belong in the decision, but so does the economic value of forage retained in the Bay.

9. "Ocean Harvesters Is an Independent American Company"

ASPN'S CLAIM: ASPN responds to Canadian-ownership criticism by emphasizing that Ocean Harvesters operates the Atlantic vessels as a U.S. company, even though Omega Protein's parent, Cooke, is Canadian.

REBUTTAL

The careful response is not to deny Ocean Harvesters' separate corporate identity. The phrase "independent American company," however, is materially incomplete if it is used to imply an arm's-length separation from Omega Protein and the Cooke enterprise.

Omega's own corporate history states that Ocean Harvesters purchased vessels formerly owned by Omega and operates them under a long-term supply relationship with Omega. Monty Deihl/Diehl's employment history provides additional continuity: ASMFC and Omega records identify him in senior Omega fishing-operations roles before he later appeared as CEO of Ocean Harvesters.

The April 21, 2026 VMRC hearing makes the relationship unusually concrete. Diehl testified as "CEO of Ocean Harvesters." Industry attorney Sean Gehan told the Commission he was appearing on behalf of Omega Protein and Ocean Harvesters. And the 2021 VMRC correspondence supplied for this review was addressed directly to "Mr. Montgomery Diehl, Omega Protein" concerning Chesapeake Bay harvest by the same reduction enterprise.

Recent reporting has also described ownership links between Ocean Harvesters, Omega and individuals connected to Cooke. Those reports should be described as reported ownership facts rather than used to claim that Ocean Harvesters lacks a separate legal identity.

> **The fair formulation is that Ocean Harvesters is a separately organized U.S. fishing company with extensive historical, personnel, operational, commercial and reported ownership ties to Omega/Cooke. Readers should receive that context when "independent American company" is offered as an answer to the ownership issue.**

10. The Regulatory Record Is More Complicated Than a Simple Sustainability Narrative

> **ASPN'S CLAIM: ASPN emphasizes regulated harvest, working-waterfront history and the economic importance of the fishery.**

REBUTTAL

Those are legitimate parts of the record, but they are not the whole record. Omega exceeded the Chesapeake Bay cap in 2019 by roughly 15,000 metric tons, or about 30 percent, prompting federal noncompliance consequences and a temporary moratorium mechanism until Virginia addressed the issue.

Bowman's 2021 letter specifically invoked that history while warning about the pace of Bay harvest. It also expressed concern about fish spills/kills and stated that two incidents over the preceding two days involved an estimated 400,000 fish spilled and presumed dead.

Omega's response deserves equal treatment. It explained that net tears can occur during pumping, that the number of escaped fish is estimated, that the company reports and monitors incidents, and that roughly half of reported spills showed no observed evidence of dead fish. It also acknowledged that in other incidents some or all escaped fish later die.

Spills are not proof of localized depletion and should not be used that way. They are relevant to the regulatory history and to the broader question of whether landed catch captures every ecological removal associated with the operation.

11. "There Is No Scientific Basis for a 50 Percent Reduction"

> **ASPN'S CLAIM: ASPN stresses that Draft Addendum II presents a 50 percent reduction as a management option, not as the output of a scientific model proving that exactly 50 percent is biologically required.**

REBUTTAL

That distinction is correct. Science has not produced a Chesapeake model showing that 25,500 metric tons is a uniquely optimal number. But management decisions under uncertainty rarely arrive with that level of precision.

The question is whether a substantial precautionary reduction is defensible. The cumulative record says yes: the cap exists to address localized risk; industrial effort is concentrated; Bay-specific abundance and movement remain inadequately measured; predator food stress is documented; pound-net indicators have raised concern; the Bay-mouth intercept question remains unresolved; and even the industry acknowledges that researchers are still trying to quantify what fraction of Bay menhaden the fleet harvests.

A 50 percent option is therefore best understood as a risk-management choice, not a claim of mathematical biological precision. Managers can revisit the level as the $4.5 million research program and other studies produce better Bay-scale information.

> **The lack of a perfectly quantified local threshold cuts both ways. It is not evidence that the current 51,000-metric-ton cap is biologically optimal either.**

Conclusion: ASPN Is Right About Uncertainty - but Draws the Wrong Management Lesson

ASPN is right about several important facts. Atlantic menhaden are not overfished coastwide. The current research does not prove that the reduction fishery alone caused Chesapeake osprey reproductive failure. Menhaden conservation alone will not rebuild striped bass. The reduction fishery supports real jobs and produces economically useful products. And a 50 percent Bay-cap reduction is a management choice, not the output of a model identifying one biologically exact tonnage.

But none of those facts establishes the conclusion ASPN wants managers to reach.

The unresolved issue is local. Chesapeake-specific abundance, movement, localized depletion and ecological effects remain inadequately known. The coastwide assessment cannot fill that gap. Ecological reference points do not certify forage sufficiency for every Chesapeake predator. Osprey studies show serious food stress. Industrial reduction effort can be concentrated near the Bay mouth. And the research now underway exists precisely because managers still lack answers to fundamental Bay-scale questions.

Waiting for science while continuing the existing level of industrial removal is not neutral. It places the risk of uncertainty on the ecosystem. A precautionary cap reduction places more of that risk on the fishery while preserving the ability to adjust management as new evidence arrives.

> *That is why reducing the Chesapeake Bay reduction-fishery cap - including serious consideration of the 50 percent option - can be both scientifically honest and appropriately cautious. The argument does not require exaggerating what the science proves. It requires recognizing what the science does not yet know.*

Method note: This rebuttal deliberately separates three categories: (1) findings established by stock assessments or peer-reviewed research; (2) unresolved risks identified by managers or scientists; and (3) advocacy claims or inferences. It does not treat lack of proof of harm as proof of safety, and it does not treat ecological warning signs as proof that commercial harvest is the sole cause.

AUTHOR’S NOTE

This commentary reflects my analysis and conclusions. I supplied the source article, public records and research direction; selected the issues to examine; reviewed and revised the arguments; and take responsibility for the final factual claims and opinions expressed here. Subject: **Atlantic Menhaden Draft Addendum II**

Dear FMP Coordinator James Boyle and Members of the Atlantic Menhaden Management Board,

Thank you for this opportunity to participate in shaping the future of the Chesapeake Bay Cap.

I am Russ Comeau of Breezy Point, NY, and CEO of Bassdozer Worldwide Fishing, LLC.

I hereby submit my formal public comments regarding Draft Addendum II to Amendment 3 to the Interstate Fishery Management Plan for Atlantic Menhaden. As a stakeholder invested in the long-term ecological health of our coastal ecosystems, I strongly advocate for management actions that prioritize the forage needs of marine predators and coastal bird species, particularly within the critical habitat of the Chesapeake Bay nursery.

1. Alignment with the ASMFC Statement of the Problem

I align with the Atlantic States Marine Fisheries Commission (ASMFC) in recognizing the escalating crisis within the Chesapeake Bay nursery, as stated in Draft Addendum II. This draft document was explicitly triggered by critical ecological warning signs:

- **Osprey Nesting Failures:** Unprecedented reproductive losses and severe food stress in the saltier portions of the Chesapeake Bay, directly linked by research to limited menhaden availability, corresponding to
- **Localized Fishery Declines:** Significant drops in catch rates and landings within the local pound net fishery, and
- **Concentration of Reduction Effort:** An unsustainable summer crowding of the commercial purse-seine fleet that threatens the wider estuarine food web.

By releasing this management action draft, the Board has acknowledged that the status quo is failing to safeguard the Bay's role as a critical national coastal nursery.

I ask the board to support the following options in Draft Addendum II. Especially, adopting Option B, Sub-Option B4 (50% reduction in the Bay Cap), managed independently, with no TAC linkage, is a clear, logical path to take to address the exact biological problems the Commission has identified.

2. Draft Addendum II: Chesapeake Bay Management Options

Addendum Section 3.1: Chesapeake Bay Reduction Fishery Cap Amount

- **Recommendation:** Support Option B, **Sub-Option B4** (50% reduction in the Bay Cap), managed independently, with no TAC linkage.

- A 50% reduction to a precautionary cap of 25,500 metric tons is the precise, protective management measure required right now to stabilize and rebuild the Chesapeake Bay menhaden bait fishery, predatory fish and bird populations in the Bay. The biological and economic stability of the Chesapeake Bay ecosystem requires an immediate precautionary management response.

- Justification: Widespread osprey reproductive failure. Recent scientific surveys indicate the osprey is suffering catastrophic reproductive losses not seen since the era of DDT. Strong empirical evidence points to low menhaden availability as the primary driver behind poor nesting success in the saltier sections of the Bay. Proponents of a 50% reduction are citing the 81% reproductive failure rate in the Bay of saltwater nesting osprey due to food stress. See link to September 2026 milestone report by Dr. Watts cited further down.

- Justification: Commercial bait fishery data points to the localized scarcity of menhaden. As verified by the independent Maryland watermen operating pound nets, this fishery sector has fallen by more than 80 percent since 2020 and currently sits below 10 percent of their permitted localized bait quota. This persistent inability to fill bait quotas is a direct economic and operational indicator of localized menhaden unavailability, deserving of precautionary measures to reduce the status quo reduction fishing quota to leave sufficient menhaden biomass to support traditional local bait fisheries and the estuarine food web inside the Bay.

Addendum Section 3.2.1: Chesapeake Bay Reduction Fishery Cap Quota Period

- **Recommendation:** Support Option B1 Even Length & Even Harvest periods (for 33%, 33%, 34%).

- Justification: Dividing the fishing year into equal periods with equal harvest limits addresses summer crowding of industrial reduction fishing effort. Option B1 ensures a steady and required volume of forage remains available for predatory fish and for adults to feed young-of-year predatory birds during peak spring and summer seasons when they have the highest biological demand for food.

- Furthermore, the 33%; 33%; 34% split helps avoid placing fishing concentration into the fall period, unlike the alternative 25%; 25%; 50% option. Fall is a critical annual period when transient migratory fish and birds depend on menhaden availability in the Bay as they stop here to gorge on baitfish to replenish body fat reserves required to continue migrating. Wildlife monitoring records show that hundreds of thousands of migrating piscivorous (fish-eating) birds utilize the Chesapeake Bay in the fall on their flight paths to western hemispheric wintering grounds in southern USA, Mexico, Caribbean, Central and South America. This points to Option B1 as a clear precautionary measure to even out menhaden availability across spring, summer, and fall seasonal needs of wildlife.

Addendum Section 3.2.2: Bay Reduction Fishery Cap Quota Period Overages & Underages

1. **Recommendation:** Support Option B (for mandatory quota period overage payback).

2. **Recommendation:** Support Underage Sub-Option 1 (Even Split and Rollover).

- Justification: A mandatory payback rule for overages ensures accountability and keeps the industrial fleet from overshooting period limits. The even split and rollover sub-option 1 for underages ensures that unused allocations do not result in highly concentrated fishing later in the season.

Addendum Section 3.3: Chesapeake Bay Reduction Fishery Cap Revisit Provision

- **Recommendation:** Support Option B (for a review at least once every three years).

- Justification: A mandatory triennial review requires the Board to regularly evaluate the cap against updated stock assessments and the shifting ecological needs of dependent predator species inside the Bay.

3. Independent Chesapeake Nursery Management vs. TAC Linkage

- Justification: The Chesapeake Bay Cap should NOT be tied to changes in the coastwide TAC. The Chesapeake Bay is a nursery, and a distinct estuarine ecological system with its own unique patterns of fishing pressure and predator forage demands. As stated in a story by the American Saltwater Guides Association, "Tying the Bay Cap to the ocean quota removes the Board's ability to manage the Bay independently and on its own scientific merits."

- The future of localized menhaden management in the Bay should start now - with a vote for a precautionary 50% reduction. Fisheries management policies explicitly allow for a precautionary approach when wildlife populations show clear signs of distress. The evidence on the osprey nesting platforms, corresponding to documented dwindling menhaden catch rates in Bay pound net fisheries, and depletion of striped bass (rockfish) makes it abundantly clear that immediate precautionary management action is the proper response to tighten sustainable limits to protect the resource before menhaden and stripers crash, and local breeding osprey colonies collapse entirely. A fishing industry argument against this is that a precautionary management approach for tighter, localized catch limits in the Bay lacks scientific justification. But waiting for absolute mathematical proof while the menhaden pound net fishery, sportfish and raptors exhibit clear signs of localized distress would be a failure of basic resource conservation.

4. Public & Private Chesapeake Bay Menhaden Research Projects

- A standalone Bay Cap under Option B, Sub-Option B4 serves as a necessary, immediate safeguard for this unique nursery. This standalone baseline will provide immediate precautionary protection during the timeframe when three independent scientific studies of menhaden inside the Bay can come up to speed. Pending Chesapeake Bay menhaden research projects include:

1. **Project 1** (the VA state track): *Chesapeake Bay Menhaden Population and Ecological Interactions Study*. With $2.0 million in state funding granted by the Virginia General Assembly directly to Virginia Institute of Marine Science (VIMS) with Virginia Marine Resources Commission (VMRC) to assess localized menhaden population and ecological interactions inside the Bay.

2. **Project 2** (the fishing industry track): *Development of a Research Roadmap for Atlantic Menhaden in the Chesapeake Bay*. With private funding primarily from the commercial fishing industry channeled through National Science Foundation's Science Center for Marine Fisheries (SCEMFIS) to VIMS and University of Maryland (UMD) to carry out the project.

3. **Project 3** (the federal track): With $2.5 million in Federal Congressional Appropriations awarded to NOAA Fisheries, transferred to the ASMFC, and allocated via an ASMFC workgroup to fund a new, independent Chesapeake Bay menhaden abundance survey designed to analyze menhaden abundance, distribution, and forage roles within the Bay ecosystem, to evaluate forage baseline data and Ecological Reference Point (ERP) modeling parameters.

- Mandate that these major scientific initiatives come online posthaste within the timeframe of the first mandatory three-year review provision. It's desirable to have the initial "scientifically defensible and ecologically meaningful" localized metrics needed to adjust the cap independently, starting with the Board's next triennial review. Going forward, the Board should rely on these new sources of targeted bay science findings, rather than permanently locking the Bay Cap into a simple fixed ratio TAC coastwide linked formula that does not account for the Bay's uniqueness as a nursery.

5. The Ecological Necessity of a Standalone, Reduced Bay Cap

The Chesapeake Bay functions as a nursery and an anchor point from which migratory baitfish species, predator fish, birds, and systemic risks move up and down the Atlantic coast. Recent declining osprey reproductivity in the Northern Mid-Atlantic (NJ, NY, CT) and into New England (RI, MA, ME) is directly linked to the health of this nursery.

Menhaden are a critical keystone forage species for the Chesapeake Bay and for the total Atlantic coast marine food web. Protecting the keystone forage fish, menhaden, in the Chesapeake Bay immediately benefits the following local and coastwide migratory species:

- **Predator Fish:** Striped bass, bluefish, weakfish, fluke, tuna, shark, cod, and more.
- **Predator Birds:** Over 65 coastal bird species, not just osprey, depend on menhaden as forage inside the Bay and along the Atlantic coast. Full list of all 65 available upon request.
- **Predator Marine Mammals:** Whales, dolphins, porpoises, seals.
- **Ecosystem Interconnected Species**: Independent Bay Cap management and monitoring trends in the Bay's menhaden population also serves as an indicator of the Bay's ecosystem

health to sustain species of high conservation concern, including Rufa Red Knot (ESA Threatened), Horseshoe Crab (ASMFC Managed Species of Concern), Black Rail (ESA Threatened), Saltmarsh Sparrow (IUCN Endangered), Atlantic Sturgeon (Chesapeake Bay DPS; ESA Endangered)and other Bay species that all benefit from a balanced ecosystem.

6. Incorporate new September 2026 Meta-Analysis Findings

A new comprehensive September 2026 report published by Dr. Bryan Watts, Director of The Center for Conservation Biology at William & Mary in Williamsburg, VA covers the Bay and the total coast from Virginia to Maine. The sweeping scope of this powerful multi-state meta-analysis points to a stark, sadly inescapable reality: the catastrophic reproductive losses first documented in the saltier areas of the Chesapeake are no longer isolated there. Across our Atlantic states, saltwater breeding pairs that depend on menhaden availability are facing an unprecedented, widespread crisis. The full report can be downloaded at:

- ***Osprey Starvation Reaches Northern Mid-Atlantic and Southern New England*** https://ccbbirds.org/2026/09/22/osprey-starvation-reaches-northern-mid-atlantic-and-southern-new-england/

Of importance to Bay Cap Addendum II , the 2026 breeding season marked the worst reproductive productivity ever recorded for osprey in the Chesapeake Bay, with average productivity dropping to 0.25 young/pair in waters above 5 ppt salinity. This severe decline is primarily driven by acute food stress and a drastic reduction in Atlantic menhaden availability. In stark contrast, pairs nesting in low-salinity tidal freshwater reaches where menhaden availability is not as critical, achieved 1.04 young/pair, surpassing the threshold required for population maintenance.

The localized findings of this report that are specific only to the Bay and to Addendum II can be downloaded at:

- ***2026 Osprey Breeding Performance Worst Ever Recorded for the Chesapeake Bay*** https://ccbbirds.org/2026/09/14/2026-osprey-breeding-performance-was-the-worst-ever-recorded-for-the-chesapeake-bay/

I align with this report. It reinforces my support for an independent Bay Cap and a 50% precautionary reduction.

In conclusion, adopting a precautionary 50% reduction and an independent Bay is a prudent path to address the exact biological concerns the Commission has identified in Addendum II. The Board must act decisively to protect the Chesapeake Bay nursery and its localized marine life, by setting precautionary menhaden reduction fishing limits. Thank you.

Sincerely,

Russ Comeau

Subject: [External] Bunker cap

Mr. Boyle,
Please reduce the amount of bunker menhaden that are fished off of our shores.
The impact is far reaching. Animals starve to death. They claim whale deaths r caused by turbines and ship strikes. The reality is that the majority have starved to death and are floating dead in the shipping lanes.
Death by starvation has been proven by autopsy.
In the matter of osprey; another sad, slow death.
In the past, osprey hunted in the bay. Now they commute to the oceanside. The fledgelings don't survive.

Fish oil is a hoax. The vitamin companies are the biggest offenders
I stopped taking fish oil and my cholesterol was reduced. CAP THEIR QUOTA!
More ice cream for me.

Kindly consider.

Sincerely,

Mara Crossin

Subject: [External] Menhaden Quotas

Dear ASMFC,
I am writing to express my concern about the decline in the osprey populations on the Atlantic seaboard, which appear to have a direct causal link to the fisheries quotas for menhaden take. Effects of climate change on the fish migration patterns, along with many other factors in the ecosystem are obviously at play, but perhaps it would be best to reduce quotas while more research is done to assess all the reasons for this precipitous decline. The osprey may be serving as the “canaries in the coal mine” and perhaps we should be paying closer attention to this warning.
Thanks for your serious consideration of this matter.
Yours,
Anne Cummings

Sept 28, 2026

Dear ASMFC,
Jame Boyle,

The Omega Plant has been over-fishing menhaden for decades and are dishonest with the excessive millions of menhaden they take and where they fish them. The CEO sends antagonistic, threatening letters to the home addresses of any residents whom express or write opinion letters to the editor in local newspapers. This over harvest is very destructive to the Bay health and many many species that feed on menhaden.

They need a cap or they will continue to harm the Bay.

Thank you

Sept. 27, 2026

Dear James Boyle
ASMFC,

Please consider our concerns: Ocean Harvesters Seine boats fishing is devastating the Bay. The adverse impacts to osprey reproduction, dolphin food source, many species of fish, the health of the Bay are destructive and possibly irreversible. We have witnessed hundreds of factory ships taking millions of menhaden. We've seen them seine net fishing directly in tiny Ingraham Bay.

Many people here did not feel comfortable attending the Northumberland hearing because the CEO of Ocean Harvesters is antagonistic, threatening if an opinion to reduce their TAC is presented. Please know that many, many people here feel Ocean Harvesters has overfished the Bay for years and years with destructive results. Thank you for considering our comments also.

Subject: [External] Bunker Fish

Please reduce the amount of fishing for bunker fish. The huge amount of fishing is reducing the most important food for Osprey and many other animals. If fishing rates stay the same , then a catastrophic decline of Bunker will leave no fish for the large fishing companies to fish, anyway. They will soon be out of business! It is in their interest to decrease their take so the fish can establish their numbers. A win win! Thank you for this opportunity to speak the truth.

October 6, 2026

Dan & Karen Doherty
PO Box 988
St. Mary's City. MD 20686

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

We are Maryland residents who have lived in St. Mary's County since 1972 and have developed a deep personal connection to the Chesapeake Bay. We live on the St. Mary's River and are avid boaters, crabbers and not so lucky fish feeders. We are deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base. We installed an osprey nesting piling in 2004 and watched our osprey families expand over the years. In the past 2 years our osprey did not produce chicks. This is clearly due to problems with food sources.

We strongly support a 50% reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

We are particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, we urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management

would provide a more precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.

There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

We respectfully urge the Commission to:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.

2. Establish firm seasonal quota periods for menhaden.

3. **Prevent excessive concentration of reduction harvest during the summer months.

4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.

5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

While our immediate focus is on our Chesapeake Bay we must consider the broader down-stream impacts on the entire ecosystem extending to the Atlantic Ocean. As the stewards of the Chesapeake our decisions have a much broader impact to our region and the entire east coast.

We appreciate that some families in Virginia may be impacted by implementing the changes that are essential. We strongly encourage all the political entities involved to develop a plan for citizens in Virginia who are impacted by the necessary changes are supported in a transition to new opportunities. A coordinated effort by the states to secure support from the federal government for affected families is strongly encouraged.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

Sincerely,

Dan and Karen Doherty

Re: Public Comment in Support of the Proposed 50% Reduction to the Chesapeake Bay Menhaden Reduction Fishery Cap (ASMFC Addendum II)

I strongly support the proposed 50% reduction to the Chesapeake Bay reduction fishery harvest cap, including distributing the allowable catch more evenly throughout the fishing season. This measure is consistent with the ASMFC Plan Development Team's own April 2026 draft recommendations and is supported by 92% of Virginia voters, according to a 2026 poll conducted by New Bridge Strategy and FM3 Research.

While I believe a broader review of purse seine netting in Virginia waters is warranted in the future, my primary request today is focused on the 50% cap reduction currently under consideration.

The ecological evidence for this reduction is compelling. The 2025 ASMFC stock assessment update revealed a 37% decline in menhaden biomass compared to previous models. Virginia's own reported menhaden bait harvest collapsed from 5.4 million pounds in 2019 to less than 1 million pounds in 2024, according to VMRC data. The consequences are visible throughout the food web: striped bass, cobia, bluefish, whales, dolphins, pelicans, and osprey all depend on menhaden as a primary food source. In the lower Chesapeake Bay, menhaden depletion is already causing measurable population-level harm to these species.

The data supporting this action is robust. A 2024 peer-reviewed study by Dr. Bryan Watts at the Center for Conservation Biology documented that only 17 of 167 monitored osprey nests in high-salinity areas of the lower Chesapeake Bay were successful, producing just 21 surviving chicks. The researchers directly linked this unprecedented reproductive failure to menhaden depletion. A subsequent 2025 study confirmed the crisis worsened Bay-wide. These findings, combined with the ASMFC's own stock assessment showing a 37% biomass decline, led the Plan Development Team to recommend the 50% cap reduction now before you.

Industry representatives continue to cite wildlife recovery data from the 1960s through 1990s, attributing population gains to the DDT ban. These references are misleading in our current context: osprey populations recovered decades ago and are now declining again specifically due to food scarcity, not pesticide exposure.

I am sympathetic to concerns about economic impact in Reedville. However, the facts are instructive: when the coast-wide quota was cut 20% for 2026, industry sources confirmed zero layoffs and no reduction in the working fleet (still six fishing boats and two run boats). A 50% Bay cap reduction is manageable. Moreover, Virginia hosts the last industrial reduction fishery on the Atlantic coast, operated by a single company (Omega Protein) owned by Canadian-based Cooke Inc. The economic benefits of this operation are concentrated in one foreign-owned firm, while the ecological and economic costs are distributed across all Virginians.

The broader economic picture favors conservation. In Virginia Beach alone, continued menhaden depletion threatens:

- Commercial fishermen's livelihoods and the restaurants they supply
- Whale and dolphin observation cruises that depend on healthy prey populations
- Recreational fishing charters and tourism
- Restaurant, hotel, and retail revenue tied to coastal tourism

These sectors represent hundreds, if not thousands, of jobs in our community alone.

The 50% cap reduction is a precautionary management measure grounded in the best available science. Even those who dispute individual studies cannot argue against the prudence of protecting our most valuable ecological resource while research continues. The cost of inaction, should the biomass decline prove as severe as current models indicate, would be irreversible.

I urge the Commission to approve the 50% reduction to the Bay cap. Thank you for your consideration of this comment.

Subject: [External] Atlantic Menhaden Draft Amendment II

Hi ASMFC,

I want to say Thank You for giving me the opportunity to voice my opinion. Being a recreational in Connecticut and spending plenty days on the water, it has been noticed the past couple of seasons that the schools of Atlantic Menhaden have been decreasing and so have the size of the fish. I fish the area between the Connecticut River and Niantic Bay out to the Race Area, which is basically the Eastern Long Island Sound. The places that we would find schools of Atlantic Menhaden like the mouth of the Connecticut River, Hatchets Reef, Black Point, Bartletts Reef, the Race and the Sluiceway have slowly become empty. I know that they are a Migratory Species but the places like Hatchets Reef, Black Point and Bartletts Reef and become thin or desolate of Atlantic Menhaden. The mouth of the Connecticut River use d to hold Atlantic Menhaden from the Spring until the Fall. Now the Atlantic Menhaden have shown up late in June and have been sporadic until the beginning of September.

I've been attending the webinars dealing with issue and have a few questions. They claim to have scientific data claiming that there is not a problem with Atlantic Menhaden, are any of these people out on the water? What's written on paper isn't a true representation of water is really happening in everyone's eyes. And also, someone funding a research doesn't always get you a fair picture either. I know that by fact as I go thru a Worker's Compensation issue dealing with work. Having Omega Protein hire their scientists has a possible Conflict of Interest. Also, if there is not an Atlantic Menhaden problem in the Chesapeake than why do they need spotter planes to find the schools to send their ships in order to catch them? What other species does the commercial sector need spotter planes to get their quota? Also in one of the graphs it should the 75% of Atlantic Menhaden is caught in Virginia, can you tell me how much is that by Omega Protein? How much is caught by their hired boats? And how about the TAC, how much do retain with both their boats and their hired boats?

Another gentleman from Virginia, with no ties to either side made a great comment about stabilization of this fishery.His comment was for the need for stabilization for that fishery for the future which they claim keeps that town employed. He sides on the side of conservation like I do. Have they ever said what these people would do for work if the Atlantic Menhaden population crashed and we needed put put very strict restrictions on Atlantic Menhaden or the resource disappeared altogether?

This species isn't just an argument about Commercial versus Recreational Sectors. This species is an important food source for many things. This is the beginning of the food chain for many fish, birds and animals. By only thinking of one impact, Omega Protein is not looking at the entire picture and evading

your responsibility of protecting a species that many depend on and need for life. That should be what we are considering and not what is good for one company.

I also attended the webinar on the TAC and one thing that I did notice is that the options that have been put out don't go far enough. None of the graphs show lines that fall below the orange and blue lines? I think the board needs to take action to stabilize the population and think about how important Atlantic Menhaden is across the board. My recommendation for the TAC is to reduce by at least 50%. We talk about the Chesapeake Bay but the Atlantic Menhaden is in trouble everywhere. The Reduction Fleet will move further out with their spotter planes and create the same situation somewhere else. My recommendations are as follows:
Chesapeake Bay Reduction Fishery Cap Amount(Section 3.1) is Option B4 25,500mt..
Chesapeake Bay Cap Distribution (Section 3.2.1) is Option B:3 Uneven length/Uneven harvest.
Quota Period Overages and Underages. I don't think the options go far enough. Overages payback but no rollover on underage. We need to save as many of these fish as possible.
Bay Cap Revisit Provision (Section3.3) Option B Bay Cap Revisited Every Three Years.
The TAC should be reduced by 50%. From the people out on the water that see this up close and personal, there is an issue with Atlantic Menhaden out here. The lack of Osprey on and along the Niantic River is another indication of a real problem. I know there will be an argument that the dominant chick will survive but when the Osprey don't return at all the following year, what does that mean? What it means is that there is no food source there. You have turned your back on River Herring, let's not do it on Atlantic Menhaden. The River Herring have not a comeback in how may years.

Thank You for giving me the opportunity to voice my opinion. Remember what nature has to lose if we don't do the right thing, Stabilization.

Sincerely,

Roman Dudus

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Mr.Boyle:

I am writing as a deeply concerned Long Island resident to submit public comments regarding Atlantic Menhaden Draft Addendum II.

Atlantic menhaden are far more than a commercial resource. They form the foundation of the Atlantic coastal food web and provide essential forage for osprey, striped bass, bluefish, whales, and many other predators. Management decisions must place the ecological importance of menhaden ahead of maximizing industrial reduction harvest.

Although Draft Addendum II focuses on the Chesapeake Bay reduction fishery, the consequences extend beyond the Bay. Menhaden are migratory, and protecting them within this vital nursery and forage area supports the health and resilience of the broader Atlantic coastal ecosystem.

I therefore urge the Board to adopt the strongest protective provisions under Draft Addendum II:

1. Select Sub-Option B4, reducing the Chesapeake Bay Reduction Fishery Cap by 50%, from 51,000 metric tons to 25,500 metric tons.
2. Establish three enforceable quota periods and select Sub-Option B2, allocating 25% of the cap to the first period, 25% to the second period, and 50% to the final period. This would help prevent an intense concentration of industrial harvest during the biologically critical spring and summer months.
3. Select the quota-period overage-payback provision under Option B so that exceeding a seasonal allocation results in a meaningful consequence rather than becoming an unenforced limit.
4. Select Option B for the revisit provision, requiring the Board to reconsider the Chesapeake Bay cap at least once every three years as scientific information develops.

I also urge the ASMFC to continue strengthening ecological reference points and to ensure that future coastwide quotas leave sufficient menhaden in the water for predators. A population cannot be considered adequately managed solely because it is not classified as overfished. Menhaden must also be available in sufficient numbers, sizes, locations, and seasons to fulfill their essential ecological role.

The coastwide 20% reduction in the 2026 total allowable catch was an important step, but stronger localized protections are still necessary. When scientific uncertainty exists, the Board should choose the precautionary alternative that protects the ecosystem rather than placing the risk on wildlife and coastal communities.

Our coastal ecosystem cannot afford passive management. The osprey, whales, recreational fisheries, and people who value the Atlantic coast are counting on the Board to protect the base of the marine food web.

Thank you for considering my comments.

Sincerely,

Karen Filauro

Re: Public Comment on Atlantic Menhaden Draft Addendum II — Chesapeake Bay Reduction Fishery Cap

Dear Mr. Boyle and Members of the Atlantic Menhaden Management Board:

I am a Maryland resident and business owner writing in strong support of the most protective action available under Draft Addendum II, and to urge the Board to go further than the range the draft currently contemplates. I ask the Board to end the industrial reduction fishery for Atlantic menhaden inside Chesapeake Bay entirely, and to pursue additional coastwide reductions of at least 50% from present levels.[1,2]

Requested Action

1. Eliminate the reduction fishery in Chesapeake Bay — a 100% reduction of the Bay Cap. If the Board concludes a full closure cannot be accomplished within this addendum, I ask that it (a) adopt Option B4 (50% reduction; Bay Cap of 25,500 mt) in a single step rather than a phase-in, as an immediate interim floor, and (b) simultaneously initiate the amendment or adaptive-management process needed to phase the Bay reduction fishery out completely on a defined schedule.
2. Reject Options A, B1, B2, and B3 as inadequate to the documented ecological emergency in the Bay, and reject any phase-in of whatever reduction is adopted.
3. Reject any Option C linkage that could permit the Bay Cap to rise above 25,500 mt. If linkage is adopted, pair C1e (13.6% of the coastwide TAC) with a hard upper limit at that level. Options C2c and C2d, which would allow a Bay Cap as high as 87,216 mt, should be rejected outright.
4. If quota periods are adopted, select Option B2 (25% / 25% / 50%), which shifts the greatest share of harvest out of the critical spring and early-summer window, together with the quota-period overage payback option so the period limits are enforceable rather than advisory.

5 Pursue coastwide reductions of at least 50% from current levels through the appropriate action, beyond the 20% reduction already adopted for the 2026 TAC of 186,840 mt.[8] Bay measures alone cannot protect a migratory coastwide stock whose Bay-bound adults are also harvested in nearshore ocean waters.

1. Menhaden are a keystone species, and the Bay's dependent predators are now failing

Menhaden are the principal energy link between plankton and the Bay's higher predators. The Commission's own management framework already recognizes this: ecological reference points for menhaden were developed using striped bass as the indicator species precisely because striped bass proved most sensitive to menhaden harvest.[9] The evidence of predator failure is no longer speculative or anecdotal.

Osprey

The Center for Conservation Biology at William & Mary reports that 2026 was the worst osprey breeding season ever recorded in the Chesapeake Bay. Productivity in waters above 5 ppt salinity averaged 0.25 young per pair across 769 monitored pairs, against a threshold of roughly 0.8 young per pair needed merely to hold the population stable. Fully 81% of those pairs failed to fledge a single chick. Productivity has fallen in each of the last three years — 0.51 in 2024, 0.35 in 2025, 0.25 in 2026 — and current reproductive rates are less than half those recorded at the height of the DDT crisis. Under current demographics the breeding population is projected to decline roughly 14% per year, about 50% over the coming decade.[3]

The cause is food, and the food is menhaden

The same monitoring documents emaciated chicks, stunted development, sequential brood reduction, abandoned clutches, and young starving in nests. In parts of the Bay, the rate of menhaden delivery to osprey nests has declined by more than 80% since the 1980s, and the resulting dietary shift has cut the energy content of osprey diets by 50%.[3] Peer-reviewed work in Frontiers in Marine Science links osprey breeding performance in the lower Bay directly to the menhaden stock index across a 1974–2021 period in which that index fluctuated more than 35-fold,[4] and monitoring of 571 nests found reproductive deficits concentrated in exactly the higher-salinity waters where ospreys depend most on menhaden.[5]

Striped bass

Atlantic striped bass has been overfished since 2019 and remains overfished under the 2024 assessment update, with a rebuilding deadline of 2029.[6] The Board is at the same time considering Striped Bass Addendum III specifically to support that rebuilding.[7] It is inconsistent to impose repeated restrictions on striped bass anglers, charter captains, and the businesses that depend on them while leaving intact an industrial fishery that removes the striped bass's primary forage from its most important nursery.

2. Menhaden also improve the Bay's clarity and water quality

Menhaden are filter feeders. Feeding in dense schools, they consume plankton and remove algal biomass from the water column. Reducing algal density improves water clarity, which in turn supports submerged aquatic vegetation and the crabs and juvenile fish that shelter in it, and lessens the oxygen depletion that follows algal die-off. Every metric ton of menhaden removed from the Bay is both forage lost to predators and filtration lost to the ecosystem. That dual service is unique to this species and is not replaced by the alternative prey on which ospreys and striped bass are now forced to rely.

3. The Bay Cap has never been an ecological limit

The current 51,000 mt cap is not derived from any Bay-specific assessment of menhaden abundance or of predator demand. It is simply an approximation of average reduction landings in the Bay from 2012–2016.[2] The caps that preceded it — 109,020 mt and 87,216 mt — were likewise set from historical landings rather than ecological need. A limit built from what the industry happened to catch a decade ago is not a conservation standard, and the Board should stop treating it as one. For the same reason, Options C2c and C2d are indefensible: they would authorize a Bay harvest roughly 70% larger than today's cap at the very moment the Bay's predators are collapsing.

It is also worth stating plainly that the Bay Cap currently equals 27.3% of the entire coastwide TAC.[1] More than a quarter of the coastwide allowable catch may be taken from a single estuary that serves as the principal nursery for the coastwide striped bass stock and hosts the largest osprey breeding population in the world. No defensible ecosystem rationale supports concentrating removals that way.

4. Scientific uncertainty argues for less harvest, not more delay

The reduction industry argues that the causes of declining menhaden availability in the Bay are unresolved and that more data is needed before the cap is cut.[10] The Commission's own record confirms the gap: the Work Group could not determine whether menhaden supply in the Bay is adequate to meet predator demand.[2] That is an argument for precaution, not for preserving the status quo.

I recognize that the 2025 single-species assessment update found the coastwide stock is neither overfished nor experiencing overfishing. But the Board itself reduced the 2026 TAC by 20% notwithstanding that finding, because fishing mortality exceeded the ecological reference point F target and fecundity fell below its ERP threshold.[8] A coastwide status determination says nothing about localized depletion within a single estuary — and localized depletion is precisely what osprey diet data, striped bass condition, and observations throughout Bay tributaries all indicate. The burden of proof belongs on the party seeking to continue large-scale industrial removals from a nursery estuary, not on the public seeking to protect it.

The asymmetry of the risks is decisive. If the Board closes the Bay to reduction fishing and menhaden availability proves to have been driven mainly by climate or distribution shifts, the cost is the reallocation of one company's harvest to ocean waters. If the Board holds the status quo and harvest is in fact a contributing factor, the Bay loses the world's largest osprey population, striped bass rebuilding by 2029 fails, and both outcomes may take decades to reverse — if they are reversible at all.

5. Timing matters as much as tonnage

Ospreys require abundant fish in April, May, and June to raise broods, and cannot shift their breeding chronology when menhaden do not arrive in quantity until late June or July.[3] Yet the landings data in the draft show roughly 30% of Bay reduction landings and 39% of effort occurring in the May 3–July 4 window, with another 54% of landings between early July and mid-September.[1] Harvest is therefore concentrated exactly when predator demand peaks. If any Bay reduction harvest is permitted to continue, Option B2's 25/25/50 distribution — which pushes half the quota into the September 13–November 19 period — is the only sub-option that meaningfully relieves that bottleneck, and it should be paired with quota-period overage payback so the periods bind in practice.

6. A Bay closure is a modest change for one company and a large one for the Bay

The operator affected here is a single vertically integrated enterprise: Ocean Harvesters, which fishes the Reedville vessels under contract to Omega Protein, reports harvesting on the order of 437,000 metric tons across its Chesapeake and Gulf operations and generating roughly $300 million in sales.[11] The Bay Cap is a fraction of that footprint, and menhaden remain available in Virginia's ocean waters. Weighed against it are the Bay's recreational striped bass fishery, its charter fleet, marinas, tackle shops, and tourism economy — including here in Annapolis — all of which depend on a functioning forage base. The company's past conduct also bears on how much confidence a lightly enforced approach deserves: in 2019 Omega Protein publicly announced it would exceed the Bay cap, and did so.[12] Whatever the Board adopts should be backed by mandatory payback provisions and meaningful accountability.

Conclusion

The Chesapeake Bay is not merely one more harvest area. It is the nursery for the coastwide striped bass stock, home to the largest osprey breeding population in the world, and a water body whose clarity depends in part on the very filter feeders being removed from it by the millions of pounds. Three consecutive years of record-low osprey productivity, an overfished striped bass stock facing a 2029 rebuilding deadline, and an 80% decline in menhaden delivered to osprey nests since the 1980s together establish more than sufficient basis for decisive action.

I respectfully urge the Board to end the industrial reduction fishery in Chesapeake Bay altogether; to adopt Option B4 without phase-in as an immediate floor if a full closure cannot be accomplished in this addendum; to reject any linkage option that could allow the Bay Cap to increase; and to pursue coastwide reductions of at least 50% from current levels.

Thank you for considering these comments and for the opportunity to participate in this process.

Respectfully submitted,

Robert Frantz

Subject: [External] Spring run

I wanted to add to the comments that I surf fish often. During the spring run in LBI I fished approx 40 days between early April and June. I have a network of friends on the island that share information daily. No adult bunker spotted. We saw a a cupcake sized small Pod one morning and that was it. Thank you Patrick A Gallen

Dear Mr. Boyle

I am pleased to submit comments on draft addendum 2 to the ASMFC menhaden fishery management plan. I am a fisheries scientist and administrator, retired from the RI Division of Fish and Wildlife (41 yrs). I have a strong background in population dynamics, having worked on numerous fish and wildlife species and issues in my career. I have represented the state on many scientific committees as well as at both the ASMFC and NEFMC. I am a past recipient of the ASMFC scientific award of excellence and my Departments distinguished service award and have served as chair of the RI Marine Fisheries Council. The osprey-menhaden issue is important to the citizens of Rhode Island as we have both a menhaden fishery and a recovering osprey population. RI once hosted a commercial reduction plant for menhaden at Pt. Judith and 1000's of Ocean State citizens treasure osprey viewing. Evidence for osprey food stress and brood reduction in RI is accruing. A supporting technical document for my comments (Gibson 2026) is available upon request.

In my analysis, I find that the osprey-menhaden tension can be distilled down to two phenomenon. First, both species collapsed in the 1960's; menhaden from overfishing and osprey from DDT contamination. Both stressors have been relieved and both species have responded with population growth. However, the magnitude of recovery is uneven with osprey achieving a much greater relative abundance. By analogy to the national debt, expenditures have grown faster than the GDP. Much of this is due to the provision of man-made nesting structures, be they cell towers or dedicated nesting structures. No additional food supply was provided to the osprey but the additional structures have incentivized conversion of osprey floaters to breeders. The birds have simply outgrown their food supply, particularly in marine waters. Brood reduction is the natural raptor response. Known as resource tracking, it has happened many times before in osprey in both the US and Europe.

Second, changing phenology is occurring in both species, exacerbating the problem in a classic match-mismatch or "wicked" problem. Studies show that climate change is causing osprey to arrive earlier to the breeding grounds. Conversely, fishery data show later arrival of menhaden in both Chesapeake and Narragansett Bays. It is not that menhaden are being depleted, they are just somewhere else when needed most by the birds. I emphasize that this is not happening in inland areas where the fish food supply is land locked under restricted connectivity. Also, food stress and

brood reduction are not yet apparent north of Cape Cod in the coastal Greenbelt region of Massachusetts.

I do not have a preferred alternative in A2. I do suggest that the action require the menhaden fishery to be separated in space and time from the critical male provisioning period of the osprey. Osprey hatchlings exhibit sigmoidal growth in their first month and energy demands are at their highest. Menhaden harvest should be delayed until after hatchlings have approached their asymptotic weight. Unfortunately, the need for and appropriate protection period may vary longitudinally along the coast. I suggest the Commission configure default options in A2, perhaps by region. The usual allowance for conservation equivalency could be afforded with state proposals vetted by a joint menhaden-osprey technical committee. You would need to establish need and osprey-menhaden overlap criterion for the defaults and custom state proposals. Although outside of ASMFC purview, I also suggest that the deployment of artificial nesting structures for osprey cease unless an enhanced food supply can be provided.

The Commission cannot change the climate responses of the fish or bird. You can only manage the outcome. My proposal will reserve locally occurring menhaden for provisioning osprey while continuing the fishery, albeit constrained to a later start. I believe this approach could be viewed as precautionary, pending results of new research funded by the Virginia General Assembly. Thank you for the opportunity to comment. I will attend the Board meeting and hope to comment in person.

Sincerely,

Mark R. Gibson

"*The more you look, the more you will see*".

Roger Tory Peterson.

Introduction-

Once nearly extirpated, osprey are now abundant, returning to RI near the Ides of March along with river herring (*Alosa sp*.). Prior to population collapse, there were 140 nesting pairs in RI around the shore of Mt. Hope Bay and along the eastern shore of Narragansett Bay (Bierregaard et al. 2014). The 1st scientific account of the osprey collapse was reported by Ames and Mersereau (1964) for the Connecticut River where populations plummeted under failing reproduction (Henny 1975). The recovery of osprey from DDT poisoning is a magnificent success story and human achievement. We are indebted to early scientists like Rachel Carson and Roger Tory Peterson who sounded the alarm. Osprey have a near worldwide distribution and are divided into four genetic groups; America, Indo-Australia, Asia and Euro-Africa (Monti et al. 2015). The America lineage is believed ancestral with splitting occurring 1.16 mya during the Pleistocene era. Based on the North American Breeding Bird survey conducted by the US Geological Survey (Sauer et al. 2020), osprey have increased in the USA at an instantaneous rate of 0.038 (SE=0.002) per year since 1966 (Figure 1). A similar rate of 0.039 (SE=0.015) has been reported for European populations (Saurola 1997). Data in Bierregaard et al. (2014) indicate the rate for the New England-Atlantic coast region was higher at 0.081 (SE=0.007). The Cornell University eBird citizen science program (Fink et al. 2023) shows important differences within that region. Northern states (DE to ME) had positive rates of increase in 2012-2022 while states from MD to FL were negative (0.099 vs. -0.027), perhaps reflecting the reproductive problems in the Chesapeake Bay and Delmarva areas. In Chesapeake Bay, population growth rate was higher in freshwater areas than marine and the two groups depended on different fish species (Glass and Watts 2009). That study showed Atlantic menhaden (*Brevoortia tyrannus*) dominated in the marine diets comprising 45% of caloric intake.

Charismatic raptors are one bright spot in an otherwise pessimistic trend in North American birds (McClure et al. 2018, Rosenberg et al. 2019, Johnson et al. 2025). The data in Figure 1 hint at a double logistic pattern, a property discussed later. Good summaries of the species are given in Henney (1975) and Poole (1989, 2019). Poole's 2nd effort includes information from modern satellite tracking studies that have shed light on the heretofore poorly understood

winter migration. New England osprey follow the Atlantic coast, fly south across Cuba and on to south American wintering grounds in the fall (Martell et al. 2001). Population recovery has been very strong in Southern New England and Long Island where the DDT pesticide residues were highest (Henney et al. 2010, Bierregaard et al. 2014). The pesticide was 1st authorized for use in 1945 and was banned by the EPA in 1972. Studies showed that it biomagnified in fish, transferred to predating osprey and inhibited calcium mobilization to their eggs (Ratliff 1967). Thin egg shells were subject to crushing and loss in the nests (Weimeyer et al. 1975). Reproduction subsequently failed and populations crashed. Production of fledglings fell to below replacement levels (Henney 1975, Spitzer 1980). The RI population declined from 140 pairs in 1940 to just 7 in 1970 (Henney 1975, Gibson 2026). Recovery began soon after cessation of DDT use in both central (Ewins 1997) and coastal areas of the US (Henny 1975, Bierregaard et al. 2014). The American eagle (*Haliaetus leucocephalus*) also benefitted from the DDT ban (Grier 1982). Sampling from 2011-2013 showed that the halogenated contaminants were no longer impacting raptor reproduction (Lazarus et a. 2016). RI osprey have increased in abundance reaching 319 nesting pairs in 2024. They are also expanding their spatial distribution since near extirpation (Dark and Clarkson 2023). The RI population at its ebb was limited to less than a dozen pairs centered in three areas; the Great Swamp in West Kingston, Chapman Pond in Westerly and in Barrington (L. Gibson, RIDFW retired- pers. comm.). Of note, Dark and Clarkson (2023) predicted eventual habitat limitations in the semi-colonial nesting species, invoking the "Information Center Hypothesis" of Ward and Zahavi (1973). Succinctly, colonies serve as information nodes to efficiently exploit patchy food resources (Greene 1987). In northern Scotland, nearly perfect logistic population growth has been accompanied by punctuated range expansions, effectuated by rare pioneering males (Maxted et al. 2026). The rate of expansion in that population was 53 km^2 per year. Given a land area of 2,678 km^2 and a similar rate, much of RI was recolonized by 2025 (Figure 2).

Osprey population growth has been fueled by the proliferation of artificial nesting platforms (Henney et al. 1974, Watt et al. 2004, MacLeod 2010, Evens and Brake 2022) apparently subverting the natural "Moffat equilibrium" (Moffat 1903, Hunt 1998). Human produced structures now dominate (95%) in the southern New England area (Bierregaard et al. 2014). Artificial structures in Finland were estimated to increase the osprey population to twice what was sustainable with natural habitats (Saurola 1997). Recovery is associated with a centennial scale reduction in anthropogenic mortality with the steepest decline since 2000 (De Pascalis et al. 2020). In that study of European migratory raptors, osprey mortality was lowest from April 10 to July 19, the breeding season. Today, anthropogenic mortality occurs mainly through fishing nets (31%), wind turbines (24%) and electrocution 18% (Garcia-Macia et al. 2024). The species is tolerant of proximity to human landscapes (Poole 1981, Forys et al. 2021) although fledgling production may be reduced to near the breakeven point (Forys et al. 2016). Well established populations can discriminate low performing sites and switch to higher performers (Harmata et al. 2007, Petersen et al. 2020). Dynamics in early recovery are dominated by philopatric behavior, high reproductive success and high female survival (Wahl and Barbraud 2005, Garcia- Macia et al. 2026, Thalhammer et al. 2026). As with most success stories, there are aberrations in osprey. Recent research in the lower, saline waters of Chesapeake Bay shows that reproduction has again fallen below that needed for sustainability (Academia and Watts 2023, Watts et al 2024, Watts et al. 2026). A 9/14/2026 press release from the CBL at William and Mary states that 2026 was the worst breeding season ever in Chesapeake Bay with reproductive success at a record low 0.25 young per pair (https://ccbbirds.org). A second 9/18 release summarizes 2026 rates from the south Atlantic to New England, showing widespread deficits mainly in saline waters. Saline areas with adequate reproduction are located north of Delmarva and south of Chesapeake Bay. Long-term monitoring data in the Bay show that the shortfall began no later than 2006 (Watts and Paxton 2007, Watts et al. 2026). They reported a decline in reproductive rate from 1.70 in 1974-1975 to 0.80 in 2006-2007 while fishing success for male osprey dropped from 2.4 to 0.4 menhaden per hour between 1985 and 2021. The researchers linked reduced menhaden abundance to chick starvation and osprey reproductive failure despite coastwide menhaden biomass increasing from 1974 to 2001 (ASMFC 2025). Food stress conclusions were reached much earlier by Spitzer and Poole (1980), Poole (1982), and Bierregaard et al. (2014) for Gardiners Bay, NY where osprey only partially recovered from

DDT but are again declining under low reproductive success. The problem is not apparent north of Cape Cod where an osprey monitoring program has been run for decades by a private land trust, the Essex County Greenbelt Association (Rimmer 2026). In this coastal region of MA (E. Boston to NH), reported data show uninterrupted exponential growth through 2026 (r_m= 0.12, SE=0.01 per year) with a mean fledge to pair ratio of 1.25 (SE=0.06) since 2013 at 18 sites. It is not known if this robust condition extends through all the Gulf of Maine but I found no agency or news media reports of current food stress north of the Greenbelt region. A Maine osprey trend was assembled for consideration in ecosystem reference points by Patel (2025). The 1966-2022 time series shows exponential growth with abundance peaking in 2016 followed by a plateau suggesting attainment of carrying capacity. In another study of Casco Bay ME osprey, DeSorbo and Gray (2015) found that reproductive success was higher in the 1980's (1.45) than in 2011-2013 (0.90) which could explain the attenuation of population growth. They suggested but did not demonstrate food limitation, possibly reduced river herring abundance.

Menhaden shortage conclusions were challenged as premature and lacking statistical rigor by Latour et al. (2024). A clear problem with the Watt et al analysis is that their integrated menhaden abundance index was for young of the year (YOY) fish whereas osprey utilize fish age II-IV. I don't know why the authors did not use the coastwide estimate of age 1+ biomass from ASMFC (2025). The YOY index displays strong hyperstability with the BAM assessment model recruitment. This means that large changes in the YOY index are not reflected in later recruits (see Appendix). Latour et al. did not dispute food induced reduction in reproductive success, aware that nesting osprey offered supplemental food had performed better (Academia and Watts 2023). Menhaden are a key prey species for osprey owing to their ease of capture and high calorie content (Durbin et al. 1983, McLean and Byrd 1991, Glass and Watts 2009). Osprey population limitation by food scarcity is not a novel observation in obligate piscivores. In Yellowstone Lake MT, osprey declined under failing reproduction when their primary prey, cutthroat trout (*Oncorhynchus clarkii*), collapsed (Baril et al. 2013). Interestingly, sympatric bald eagles with a more diverse food supply, endured. In an Oregon reservoir treated with rotenone to eradicate undesirable fish, osprey reproduction was adversely impacted, and food limited brood reduction occurred (Henny and Kaiser 2022). Acidification that reduced lake fish populations, temporarily reduced breeding success in Sweden and Finland until liming restored fish production (Eriksson and Kellin 1994, Saurola 1997). In the Missouri River, MT osprey selected nest sites in accordance with fish availability, more near shallow reservoirs and less near rivers (Harmata et al. 2007). Finally, Murry River osprey in Australia were extirpated when invasive carp clouded the water preventing prey detection (Detmar and Dennis 2018). Growth of young osprey is very rapid with chicks approaching adult weight in just 40 days (Steidl and Griffin 1991, Schaadt and Bird 1993). Weight gain is critical given the long migrations they face after fledging, highlighting the importance of abundant fish prey. Food shortage and starvation can lead to osprey brood reduction (Poole 1982, Hagan 1986). It has been estimated that a breeding pair raising two young need 375 pounds of fish per season (Nordbakke 1980) or 1.75 pounds per day (Academia and Watts 2023). Prey size is important, requiring optimization between energy content and handling constraints. In Scottish lakes, prey size distributions were unimodal with most prey between 26 and 30 cm in length (Carss and Godfrey 1996). Similarly, Glass and Watts (2009) reported mean prey lengths of 23.7 cm and 22.2 cm in upper and lower regions of Chesapeake Bay, well above YOY menhaden length. Growth curves in Reintjes (1969) indicate ages 2-4 menhaden would be preferred.

The menhaden-osprey tension may be part of a much larger dynamic in osprey. While reviewing the Cornell University eBird data, I noticed an unusual pattern on a large scale across the Americas. In 49 US states, osprey trends from 2012 to 2022 were positive in 41 cases (P= 0.837, SE=0.053), with the Atlantic coast hosting the negative outliers. However, in Canada all 13 cases across the provinces showed negative trends. This is contrasted with Mexico where 28 of 30 jurisdictions had positive trends (P=0.933, SE=0.046). Similar positive proportions were found for countries south of Mexica and in the Caribbean islands. More detailed analysis is beyond the scope of this work but weakening populations in the northern range and strengthening in the south suggest climatic effects on population biology. This

is reflected in counts of fall osprey migrating south at Hawk Mountain, PA (Figure 3). The citizen count time series is remarkably long, recapitulating the pre-WW II recovery from persecution, the DDT effect and recovery but a recent downward trend not explained by a standard logistic model. A substantial new mortality agent or alias in 2003 is needed to model the data. These are birds from the north not the Chesapeake Bay-Delmarva area that is ground zero for food stress. A possible explanation is shortening of migration routes that has been observed in Europe (Martin et al. 2019). It is well known that some osprey populations are not migratory (Poole 1989). These generally occur in the southern range for example on the Canary Islands (Rodriguez et al. 2013), in Baja Mexico (Castellanos et al. 2018) and in south Australia (Detmar and Dennis 2018). Northern, migrating populations "leap frog" the resident populations to overwinter (Monti et al. 2018a). Intermediate populations exist in Florida and the Mediterranean where some migrate, some do not, and those that do move shorter distances (Monti et al. 2018b, Forys et al. 2021). These observations suggest great plasticity in osprey migratory behavior, varying spatially and temporally (Martell et al. 2001). It is possible that osprey writ large are eschewing long-distance, demanding migrations in favor of more localized distributions. This would explain the rarefaction of Canadian populations, diminished fall migrants from the north and the concentration in Mexico. It begs the question what selection pressure could cause this? Migration is an evolutionary adaption to enhance fitness in the face of seasonal changes in resource availability (Gu et al. 2024). Among the benefits are; access to food, predator avoidance and reduced competition. As a specialist piscivore with longevity and delayed maturation, osprey life history is finely tuned to accommodate a long migration. If one or more benefits are lost, natural selection may adjust migration (Winger et al. 2025. Satellite telemetry has revealed that north American osprey are sedentary energy conservers on their wintering grounds (Washburn et al. 2014). The obvious 800-pound suspect is climate change (Zurell et al. 2018). Widespread advances in spring avian migration are occurring in response to increasing temperature (Usui et al. 2017) but phenological tracking by the birds is delayed (Adams et al. 2025). It may be that the winter southern range was ancestral in osprey with spring, northward migration developing as constrained by annual winter ice conditions and periodic glaciation (Zink 2011).

In this study, I revisit and extend the Bierregaard et al. (2014) and Gibson (2025) analysis for RI osprey. Those studies covered pre and post DDT periods, the latter directly incorporating DDT application as a sink term in a logistic population model. It showed that RI osprey reached a low of 6 breeding pairs in 1972 but recovered to over 300 by 2025. This study is restricted to the post-DDT, 1974 to present period. I use the RIDFW census data, continued by the Audubon Society of Rhode Island (ASRI- Dark 2025). I augment that data with information from other populations as necessary in the spirit of the Punt at al. (2011) Robin Hood approach. An extensive literature search was done using key words "osprey population dynamics, decline and recovery, survival rates and modeling". I apply a two-stage, catch-survey type model to the combined RIDFW-ASRI data set (Collie and Sissenwine 1983, Mesnil 2003). Given the findings of Bretagnolle et al. (2008), Wahle and Barbraud (2013), and Garcia-Macia 2026) I test for evidence of density dependence in the growing RI population. They found that fledgling survival was inversely related to floater abundance in recovering populations in Corsica and France while in Spain population growth was arrested by density in just over a decade. I also examine menhaden stock status as it relates to performance of RI osprey. The forage species has been called the "most important fish in the sea" in a popular book (Franklin 2007). In recognition of their great ecological value, the Rhode Island Division of fish and Wildlife (RIDFW) developed an assessment and management system for menhaden in Narragansett Bay (Gibson 2007). Ironically, RI was the first state to host a menhaden reduction plant (Anstead et al. 2021) and a large commercial fishery operated in the 1960's and 1970's (Oviatt et al. 2003, Gibson 2007).

Methods and Data Sources-

RI Osprey Population- Data for the RI osprey population was taken from RIDFW federal aid reports (L. Gibson- Osprey Newsletters), Henny (1975), Henny et al. (2010), ASRI reports (Dark 2024) and Bierregaard et al. (2014). These data covered the period post-DDT, 1977-2026. RI data for 2026 is preliminary but included because of growing awareness

of a change in osprey demography along the Atlantic coast (S. Brown, ASRI- pers. comm.). Other vital rates such as survival, population growth, longevity and brood size were summarized from the literature. I note that the ASRI data may reflect a methodological change for 2023-2026 making it more difficult to parse the nesting data by stage (Dark 2025, pers. comm. 2025). Difficulty in enumerating raptors has been discussed by Fuller and Mosher (1981) and cautions about citizen science expressed (Panuccio et al. 2019, Steiner et al. 2022). For the 1977 to present data set, I extracted the number of active, breeding nests and fledglings produced. Active nests are those with adult breeding activity noted while housekeepers and "floaters" are believed to be age II birds returning from wintering grounds for the 1st time but not breeding (Henny and Van Vilzen 1972, Poole and Agler 1987, L. Gibson-pers. comm.). They differ in that housekeepers pair and build nests while floaters remain single and cryptic. ASRI reports enumerated housekeepers from 2010 to 2022. The average count was 11.31(SE= 1.94) compared to an average breeding pair count of 152.0 (SE= 6.93) for the same years, a percentage of 6.9%. That is consistent with the 5% to 10% range given in Henny and Van Velzen (1972). It is also consistent with publicly available information on Marthas Vineyard where housekeepers, enumerated by experts Gus Ben David and Dr. R.O. Bierregaard, where they constituted 3.5% to 11.1% of the nesting population from 1998 to 2006 (https://ospreymigration.org). In a rare enumeration in Corsica, floaters increased from 3.7% to 16.4% of the population as it approached carrying capacity (Bretagnolle et al. 2008).

In theory, housekeepers (and floaters) are important as they constitute the replacements for lost breeders. However, the existing ASRI housekeeper enumeration was terminated in 2023 so I could not include them in modeling. I am not aware of any study or quantification of osprey floaters in RI. They tend to be younger than breeders (Vali et al. 2021) and are notoriously hard to study because of their cryptic, secretive behavior (Sergio et al. 2009, Hunt and Law 2023). Accounting for these groups in RI is a prime topic for future research. Much has been made of floating strategy in the raptor literature since the linkage between territorial and floater component dynamics was illuminated (Moffat 1903, Brown 1969, Penteriani et al. 2005). The scientific understanding of floating has shifted from a view of floaters as failed, nuisance individuals to an essential population component (Penteriani et al. 2011). They function as a reserve of potential breeders (Hunt 1998, Penteriani et al. 2011) unless they decline to breed under food shortage as shown for northern goshawk (Rutz and Bijlsma 2006). Replacement of lost osprey breeders by floaters occurs rapidly, within 48 hrs. along the Yellowstone river (Restani 2023). A growing proportion of surviving but recruitable non-breeders create density dependence in reproduction (Bretagnolle et al. 2008, Lenda et al. 2012, Sergio et al. 2017).

To model the RI recovery, I modified the fisheries catch-survey model (CSA) of Collie and Sissenwine 1983, and Mesnil 2003) for the two, quantified age groups, fledglings and adults:

$$N_{t+1} = [N_t * \exp(M_1) + R_{t-3} * (\exp(M_2) * (\exp(-M_1 * 2))^{\wedge}\beta)] * \exp(\delta_p) \qquad (1)$$

where: N= adult nesting pairs

R= number fledglings

M_1= adult mortality rate

M_2= 1st year fledgling mortality rate

β= density dependent term

δ= process error term

t= time

and

$$R_t = \alpha * N_t \hat{} b * \exp(\delta_p) \quad (2)$$

where: α= slope at origin

b= curve shape parameter.

Eq.1 allows for density dependence in the period from fledgling to adults. Eq. 2 is a nonlinear curve where alpha is the maximum rate of fledgling production subsuming clutch size and early brood survival. The parameter b is the shape parameter imitating density influence. It is not commonly used in parent-progeny relationships as it lacks a theoretical limit but is flexible and able to model proportional (β=1.0), negative (β<1.0), or positive (β>1.0) relationships between adults and fledglings over the data range. The latter could occur for example under Allee effects. Eqs.1 and 2 are the population dynamics process. State variables are related to observed quantities as:

$$n_t = q_n * N_t * \exp(\delta_o) \quad (3)$$

and

$$r_t = q_r * R_t * \exp(\delta_o) \quad (4)$$

where:

q= catchability or detection probability

n,r = observed counts

δ= observation errors.

Substitution of eqs.3 and 4 into eqs.1 and 2, combining error terms, yields the full estimation model. Note that there is no harvest term in eq.1 as in a fisheries-oriented CSA. Osprey are a protected species so the sink harvest term in CSA is replaced with constant instantaneous mortality rates. Note also that without housekeeper and floater counts, the fledglings (recruits) enter the breeding population at lag 3 through a compound mortality rate. “Knife edge” recruitment is assumed which is technically incorrect but necessary without age-structure and breeding history data. It is known that some age 2 osprey participate in breeding (Englund and Greene 2008) and some delay 1st reproduction beyond age 3 (Morandini et al. 2019). The effect of a knife-edge assumption when recruitment is actually platoon is the reverse of the aging error problem in catch-age analysis. Aging error in catch attenuates recruitment variability aka the “smearing” effect (Bradford 1991). Knife-edge recruitment in eq.1 focuses incoming recruitment on a single fledgling cohort rather than a platoon of cohorts thereby increasing the variance in modeled adult pairs. Because of the extended longevity in adult osprey, this is not expected to be a significant source of bias. As formulated, the mortality rates in eq.1 are confounded and need a constraint to separate. This was done by using the mean juvenile to adult mortality ratio from the Newton et al. (2016) raptor compilation i.e. M2≈ 2.614*M1. Housekeepers and floaters could be modeled if reliable data becomes available. Model parameters were estimated by minimizing the squared residuals between observed and model estimated N and R using SOLVER assuming log-normal error. The modified Gauss-Newton GRG algorithm was employed in Excel Solver for nonlinear problems. Uncertainty in parameters was assessed using the jackknife procedure of Tukey (1958). This nonparametric method was preferred over the usual inverse Hessian calculation of asymptotic variances because of the distorting effect of imposed constraints (Efron and Tibshirani 1993). Full estimation of eqs.1 and 2 i.e. separating process and observation errors would require additional information and a state-space, Bayesian treatment. That is beyond the scope of this study and data set so only combined error was considered.

Without harvest losses, there is no scaling information to inform q parameters so they were constrained to 1.0. This effectively renders eqs. 3 and 4 identical to 1 and 2 under only process error. I did not regard this as a major issue as the ratio of observation to process error tends to decline with time series length (Ahrestani et al. 2013) although precision on abundance may be reduced (Thorson and Minto 2015). The RI time series is long, encompassing at least 5 generations of osprey. A high and constant detection probability can certainly be challenged (McCallum 2005) but further advance on this front require details on the evolution of the RI counting program that transitioned from a government agency to a non-profit entity. Particularly important is how counting effort has been deployed as the population grew and dispersed (Nolte et al. 2016). A detection requires that a counter be present (availability) and actually see a nest (detection). If spatial deployment of counting effort has not kept pace with population dispersion, detectability would decline. In fisheries, climate induced population redistribution is causing progressive misalignment of fish with fixed survey strata (Bell et al. 2022). Additional information for full estimation could include Bayesian priors for mortality rates and detection probabilities from other raptor studies. Additional osprey abundance indices say from the North American Breeding Bird Survey or Cornell University e-bird program could be considered for model tuning. Future analyses will need to consider changes in survey effort. Participation in the ASRI osprey counting program has grown over time increasing from 60 to 152 individuals from 2010 to 2026 (5.5% per year). Consultation with the RIDFW former project leader indicated it is much higher now than when she took over the program in 1978 (L. Gibson- pers. comm.). If a robust counting effort series can be developed, it could be used in the assessment. A temporal tally of artificial nesting structures deployed would also help in considering changes to carrying capacity. Under a q=1.0 assumption, populations estimated via eq.1 and 2 are minimum estimates. If q is changing, the steepness of population increase could be biased. For example, the ASRI nesting count from 2010 to 2025 increases at an exponential rate of 0.076 per year but if raw counts are adjusted by count participants, the rate drops to 0.027. Drone monitoring could be an effective addition from the agency to augment and enhance the ASRI human effort particularly in remote areas (Murphy et al. 2026). A random-stratified design with ranging detection could support a line transect estimation of RI osprey. Alglave et al. (2022) provide a method to combine design-based scientific surveys with spatial harvest data generated by searching fishers.

In ecology, the intrinsic rate (r_m) is considered akin to Newton's 1st law of motion (Turgeon 2001). It is foundational to population dynamics (Sible and Hone 2002), determining a species ability to sustain harvests as well as recover from disturbances (Cortes 2016). The intrinsic rate is defined as the difference between birth and death rates and is best estimated in populations recovering from low abundance as is the case for osprey (Caughley and Birch 1971). They emphasize and I reiterate that realized rates of increase may be less than the maximum depending on abundance relative to carrying capacity. R_m is related to alpha of eq. 2 as $r_m = \ln(\alpha)$. Intrinsic rate is inversely related to body mass across many animal taxa and orders of magnitude in mass (Fenchel 1974, Brown et al. 2004, Brammer et al. 2022). For example, Neil and Lebreton (2005), found that r_m declined from 0.77 per year in the 20-gm rock sparrow (*Petronia petronia*) to 0.09 in 8,000 gm Griffon vultures (*Gyps fulvus*). Published regressions predict a r_m of 0.101 for 1,700 gm osprey. Both Houghton and Rymon (1997) and Watts et al. 2004) provide estimates of population recovery rate in osprey, the former nationwide and the later in Chesapeake Bay for context.

Because of the considerable controversy over the state of the Atlantic Menhaden population and osprey food supply, I examined the long-term data on the coastwide and local stock. I understand the nuance between overfishing and localized depletion having dealt with it for a time as RI administrative commissioner to the ASMFC. Still, concerns about menhaden supply and osprey have been expressed beyond Chesapeake Bay (Bierregaard et al. 2014, NJDEP 2026). The ASMFC conducted a benchmark menhaden assessment in 2019 that was updated in 2025 including a change in the natural mortality rate, M used (ASMFC 2025). That change has been challenged (Ault and Luo 2026) and will be reconsidered in a new benchmark to be conducted in 2027. The disagreement centers on the magnitude of the age-specific but time invariant vector. More important in my view is the possibility of time varying M (Drew et al. 2021).

For now, the ASMFC (2025) results are the best available science. I downloaded biomass estimates, fishery landings, and recruitment data for years 1955-2023. I also examined information from the RI Division of Marine Fisheries (RIDMF) on menhaden abundance in Narragansett Bay from surveys and spotter pilot counts (Gibson 2007, N. Lengyel-Costa, RIDMF 2026- pers. comm.). Adult menhaden appear seasonally in the Bay and their abundance was recently shown to vary with water quality (Ianniello 2026).

Case Study Florida Osprey- The case study examined osprey data from the Florida breeding bird survey from 1966 to 2020 (Tringali 2023). The length of the time series encompasses part of the DDT era (1966-1972), and some peculiar demography relevant to RI warranted review. The FL population has spread geographically and increased by a factor of five in association with use of artificial structures and reservoir construction (Tringali 2023). This suggests changes in habitat carrying capacity in addition to relief from DDT. Following Gibson (2025) and Maxted et al. (2026), I obtained the count data and fit a discrete time step, logistic population model. Assuming detection probability is 1.0, the model is:

$$n_{t+1} = n_t + r_m * n_t * (1 - n_t/K) \qquad (5)$$

where: n= population size in survey units

r_m= intrinsic rate

K= carrying capacity

t= time.

The estimated model was subject to residual diagnostic analysis including autocorrelation.

Results and Discussion-

CSA Model- Figure 4 shows the trend in active osprey nests in RI along with the estimated CSA model. They increased from 12 in 1977 to 302 by 2025. Contrast this with the 140 pairs reported from the 1940's prior to DDT usage (Henney 1975, Bierregaard et al. 2014). The preliminary 2026 estimate is shockingly low at 204, falling well off the model trend. It suggests either a major adult mortality event, failure of housekeepers and floaters to recruit, or abandonment of nests. Fledgling production increased long-term, from 19 to 295 young (Figure 5). As with the adults, 2026 fledgling production (176) is well below the model trend. The two-stage model fit was acceptable with most parameter coefficients of variation of 9% or less. The intrinsic rate coefficient (r_m) was less certain (CV=26%). There is a strong residual pattern with an opposing trend between adults and fledglings becoming extreme in 2024 (Figure 6). Importantly, neither residual set was correlated with coastwide or RI menhaden abundance. The midway expansion in variance coincides with takeover of the monitoring program by ASRI. This is not a criticism of the ASRI effort, simply acknowledgment of model diagnostics and the possibility of nonstationary in the population dynamics. Trial CSA model runs with either changes in catchability or mortality were needed to moderate the residual pattern. I cannot discount either factor given the change in data collector and ongoing osprey food shortages. A more advanced, state-space CSA model integrating auxiliary data would be useful to evaluate competing hypotheses. Additional data that could be brought to bear include menhaden abundance and the number of artificial nesting structures deployed. Model parameter estimates are given below in Table 1.

Table 1- Parameter Estimates to RI Osprey CSA Model

Parameter	Symbol	Estimate	SE	CV
Alpha	α	1.07600	0.06400	0.05948
S-R Beta	b	1.05300	0.01640	0.01557
Initial Nest	N0	12.22900	1.11870	0.09148
Adult M	M1	0.23100	0.01260	0.05455
Juvenile M	M2	0.60400	0.03690	0.06109
Juv M Beta	β	0.89300	0.02100	0.02352
Intrinsic Rate	rm	0.07400	0.02000	0.27027

The adult mortality rate of M1= 0.231 corresponds to a survival rate of 0.794. The Newton et al. (2016) compilation of raptor rates produced a mean adult S= 0.773 (SE= 0.015) for 75 raptor species, good agreement with the CSA. Longevity models based on maximum age (Dureuil and Froese 2021) estimate S=0.81 to 0.85 for an osprey longevity of 20 to 25 years (Henny and Wight 1969, Ryttman 1994, Maxted et al. 2026). The RI juvenile M2 rate corresponds to S=0.547. Newton's juvenile data was more limited, with a higher mean of S= 0.686 (SE= 0.047) for 22 cases. Survival rate in birds is correlated with body mass and birds have higher survival than fish and mammals for a given mass (McCoy and Gillooly 2008). The CSA model results suggests that RI osprey have mortality rates typical of raptors writ large, at least through 2024. Vali et al. (2021) and Anderwald et al. (2021) also found that juvenile osprey survival was less than in adults in Baltic and Polish populations. The difference between the RI (0.55) and Baltic and Polish (0.21-0.33) estimates may frame a critical juvenile survival threshold since both European populations were in decline. Survival rates are critical life history traits in long-lived raptors with low reproductive output (Tack and Noon 2017, Monzon and Fredenberg 2018, Thalhammer et al. 2026). Using the approach in Bird et al. (2020), I estimated a generation time of 8.2 years for RI osprey.

The relationship between RI nesting pairs and fledglings produced is plotted in Figure 7. Non-linearity is evident and an asymptote or carrying capacity may be manifesting. The estimate of b was 1.053, significantly greater than 1.0, suggesting positive density dependence at low breeder abundance. The 2025 and preliminary 2026 data suggest a retreating population, possibly showing hysteresis. To properly fit the fledgling data in Figure 7, a generalized stock-recruitment model with an additional inflexion parameter would be needed such as the logistic offered by Maunder (2022). The sigmoidal pattern in Figure 7 could be explained by an Allee effect at low population size. A plausible mechanism for positive density dependence at low population size is group benefits as initially proposed for goldfish by Allee and Bowen (1932) and for osprey by Hagan and Walters (1990). Neophyte animal populations may benefit from increasing numbers through several mechanisms including mutual defense, assisted care, and information exchange (Muir et al. 2024). Birds may show lags in the onset of exponential growth (Aagaard and Lockwood 2014) with newly established osprey populations in both France and Spain showing lags of one generation (Wahl and Barbraud 2014, Garcia-Macia 2026). Chen et al. (2002) shows how to incorporate an Allee effect in common stock-recruit models. The fledgling to pair ratio or slope at the origin was estimated at 1.076 (SE= 0.064), in the range needed for sustainability (Henny and Wight 1970, Spitzer 1980, Poole 1989). Reproductive success in RI was not always sustainable. During the DDT era, RI fledgling per breeding pair plunged to a low of 0.27 in 1960 (Henny and Byrd 2010). Two decades of low reproductive success were catastrophic for the population (Figure 8). Following cessation of DDT use, success climbed and from 1994 to 2021 the rate averaged 1.44, well above the 1.15 standard adopted for Chesapeake Bay (Watts et al. 2024). Of concern are the recent RI rates from 2022-2026 where a clear decline to below

this standard is evident. This decline is associated with a drop in the proportion of successful nests. Because of brood failure or nest desertion, the proportion has dropped from a long-term mean of 0.84 (SE=0.07) to 0.66 (SE=0.03) from 2023 to 2026. Long-term RI osprey reproductive success was positively correlated with the local menhaden abundance index but only weakly so (r=0.29, P=0.046). However, the correlation is much stronger when considering only recent data for 2010 to 2026 (r=0.66, P=0.003). Recent low success is coincident to a reduction in RIDFW spotter pilot menhaden abundance. This suggests that as the RI osprey population has grown, so has the importance of menhaden. Data from the CT Audubon also shows a recent decline in reproductive success. This may reflect asymmetric brood reductions under food stress. Evidence is growing that this problem stretches beyond Chesapeake Bay (Watt et al. 2026, NJDEP 2026). Food stress in coastal, as opposed to inland areas, seems to be the cause. The phenomenon should be watched closely in RI for evidence of food shortage and asymmetric brood reductions.

Dark and Clarkson (2023) used a general linear model (GLM) to explore relationships between several abiotic and biotic variables influencing successful nesting in RI. Their best predictor of nesting pairs was fledgling production two years before reflecting a year sabbatical of age one birds (Poole 2019). That relationship is shown in Figure 9 with a more realistic three-year lag. The CSA model estimated a density dependence effect in the juvenile mortality rate with β= 0.893 (SE= 0.021). The estimate is significantly less than 1.0 suggesting that fledgling survival has an inverse relationship with abundance as found in a recovery population in France (Thalhammer et al. 2026). Because of model structure and data limitations, it cannot be determined exactly where in the recruitment lag the effect manifests. Based on satellite tracking, the spring migration is the year quarter where the greatest mortality occurs in osprey (Klaasen et al. 2014). The estimated RI density effect could occur anywhere between 1st migration and recruitment back to the breeding population. Admittedly, this is not very satisfying as the recruitment lag covers three years over a large spatial expanse from RI breeding to Caribbean overwintering grounds (Martel 2001). It is the penalty of not having reliable census data on the age 2 housekeeper/floater contingent.

The intrinsic rate of increase in RI osprey since 1977 was estimated at 0.074 (SE=0.020). This is above the realized 0.060 (SE= 0.002) average for 16 sites around the Chesapeake Bay in Watts et al. (2004) but below the nationwide realized mean of 0.090 (SE=0.010) for 34 states in Houghton and Rymon (1997). It is below the 0.101 maximum rate predicted from various allometric models based on body weight (Fenchel 1974, Brammer et al. 2022). A lower r_m than predicted by life history may reflect residual DDT effects. The Houghton and Rymon (1997) compilation shows a wide range with highest rates where DDT usage was minimal. Osprey are a long-lived species that produce one brood per year, have low clutch size and delay reproduction; all factors associated with low r_m (Brewer and Swander 1977). It is possible that r_m is nonstationary in Atlantic coast osprey given the emerging food supply issues (Watts et al. 2024, 2026). Figure 7 suggests a nonstationary and backward-bending production curve. These are common in exploited fish stocks such that the recovery path differs from the decline path i.e. hysteresis (Walters et al. 2008). In fish stocks, the pattern emerges when there is a decline in recruitment unrelated to parental stock level as would be the case under food stress and brood reduction. Replication of low fledgling production in 2027 and beyond could be revealing.

Deterministic 10-year projections of the RI population made under several recruitment scenarios are shown in Figure 10. The CSA 2026 estimated number of breeding pairs was projected ahead 10 years using the CSA mortality rates and three recruitment scenarios; 2026 RI breeding success, mean RI success, and the 2026 Chesapeake Bay rate. If RI breeding success remains at the 2026 reduced rate of 0.86, the population is projected to decline to 255 pairs by 2036. Under average success (1.38), the population grows to 381 by 2036. Under a doomsday scenario of the 2026 Chesapeake Bay success rate (0.26) the population declines to only 125 pairs. A break-even point for RI stability was determined to be 1.03 fledglings per nesting pair. These findings are in general accord with Henny and Wight (1969) who found osprey sustainable rates of reproduction are inversely related to survival and longevity. A tradeoff between 1st reproduction and longevity is a fundamental element of life history theory (Stearns 1992) but correlative studies

have not found strong evidence (Winder et al. 2025). However, selective breeding experiments have demonstrated it (Tschirren et al. 2026). While a short-term RI population decline seems inevitable, the longer-term response is unclear. A reduced population could vacate territories allowing for remaining osprey to breed earlier (Stewart et al. 2025) thereby increasing population growth rate (Cole 1954). The interaction between living spaces and food supply will likely be determinate as was the case in German red kite (Katzenberger et al. 2021). Without knowledge on the cryptic RI floater population, more precise predictions cannot be supported.

Atlantic Menhaden and Osprey Food Supply- Biomass of age 1 and older Atlantic menhaden from the most recent update of the benchmark assessment (ASMFC 2025) is shown in Figure 11. Menhaden biomass dropped substantially from 1959 to 1973 under overfishing which was coincident to the DDT effect on osprey. Biomass then rose until 1992 in synchrony with osprey recovery nationwide (Figure 1) and has stabilized well above the 1970's low point. Menhaden abundance in Narragansett Bay shows a somewhat different pattern (Figure 12). Ichthyoplankton data, fishery data, and fishery independent surveys described in Gibson (2007) and Ianniello et al. (2026), updated and blended by Z-score method shows high abundance in the 1970's, collapsing during 1984 to 1996 before recovering to medium levels in 1997-2023. Recent abundance, driven by the RIDFW spotter pilot school counts, is low. The menhaden collapse and recovery are approximately a decade later in Narragansett Bay than coastwide. Asynchrony in menhaden population dynamics on a north-south axis has been shown before by Buchheister et al. (2016). Narragansett Bay menhaden have not achieved former levels of abundance possibly due to a long-term decline in Bay plankton abundance and strength of the winter-spring bloom (Friedland et al. 2011, Thibodeaux et al. 2024). During menhaden recovery, the osprey population in Chesapeake Bay was increasing from 1,450 pairs in 1973 to 3,500 by 1995 (Academia and Watts 2023). It now stands at approximately 10,000 (Watts et al. 2026). Combined with the ASMFC (2025, 2026) menhaden assessments, the ratio of coastwide menhaden biomass to Chesapeake Bay osprey numbers has declined from 0.66 kilotons per pair to 0.16, not because of a decline in menhaden but rather osprey have increased more in abundance. A quadrupling of the coastwide menhaden stock is needed to restore the ratio, assuming the proportion entering Chesapeake Bay is constant. It is not surprising that the proportion of menhaden in osprey diets has declined (Glass 2008). A similar increase in menhaden entering RI waters would be needed to restore the local menhaden/osprey ratio to that which existed during initial RI osprey recovery in the 1970's when menhaden were abundant and up to 20 KT were taken annually from Narragansett Bay (Durbin and Durbin 1998). These observations gives me pause with regard to the hypothesis of menhaden depletion by commercial fishing. I do not understand the Watt et al. (2024) conclusion that we must return to the 1975-1985 menhaden population status. As is clear in Figures 11 and 12, that was a low point for menhaden relative to 1990-2023. Achieving the 1975-1985 prey/predator ratio, would require a massive increase in coastwide menhaden biomass from roughly 1,900 KT to 7,600. Evidence for density-dependent growth (Reish et al. 1985, Houde et al. 2016, Schueller and Williams 2017), dome-shape production (Schaff and Huntsman 1972) and over compensatory recruitment (Vaughan and Merriner 1991) in menhaden suggest this is impossible (see Appendix). An overlooked finding in Glass and Watts (2009) is that upstream reaches where osprey reproduction is sustained, gizzard shad (*Dorosoma cepidianum*) not menhaden dominate, and prey energy density was 66% higher. This suggests an energy acquisition problem not menhaden per se.

Climate change is having widespread and diverse effects on marine fish (Nye et al. 2009) and raptors (Martinez-Ruiz et al. 2023). In addition to recovery from overfishing, menhaden may have changed their phenology and distribution, causing localized shortages i.e. the proportion utilizing certain areas has not been constant. Menhaden distribute latitudinally by body size (June 1972, Ahrenholtz 1991) so recovery of age structure from overfishing may be occurring, favoring the Gulf of Maine. A new paper, using hydroacoustic and mid-water trawl surveys, documented a dense overwintering population off the coast of NJ dominated by age 3-4 menhaden (Nesslage et al. 2026). Climate warming is inducing a northward shift in distribution of many fish species (Nye et l. 2009, Langan et al. 2021) and it has

occurred before in menhaden during a 1950's warming trend (Dow 1977). The species demonstrates a north-south difference in recruitment pattern that is out of phase and correlated with the Atlantic Multidecadal Oscillation (AMO), a low frequency pattern in sea-surface temperature (Buchheister et al. 2016). Larval distribution and timing has changed in the NE US continental shelf to an earlier and more offshore distribution (Walsh et al. 2015). Consequently, Chesapeake Bay no longer produces a majority of recruits to the population supporting a distribution shift (Anstead et al. 2017). A latitudinal shift is supported by index residual patterns in ASMFC (2025). The northern adult index trends to positive residuals in recent years while the southern index trends negatively. The mid-Atlantic adult index shows no trend overall or in recent years. In the Gulf of Maine, menhaden abundance is periodic with menhaden being absent from 1994 to 2015 but present in fishable quantities since 2016 (Cieri 2024). The reappearance of menhaden in the Gulf is associated with a shift to a warmer temperature regime in 2012 (Chang et al. 2026). Changing timing and spatial availability of menhaden could have significant impacts on an obligate piscivore in coastal nesting areas. NJDEP (2026) has reported that food stress occurs in marine areas of NJ but not in their inland ospreys, confirming Watts et al. (2026). The lack of evidence of food stress in the Greenbelt region of coastal MA cited above is noteworthy.

More evidence of changing menhaden phenology can be found in ASMFC (2026) where the prosecution of the reduction fishery in Chesapeake Bay is shifting to later periods within the year. From 2018 to 2024, the date of 50% cumulative landings has shifted later by approximately 6 weeks. Presumably, industry fishing under a regulated quota and start date (51 KT, May 1st), fishes economically when menhaden are in quantity. Historically, menhaden primarily overwintered south of Cape Hatteras, NC (Nicholson 1972, 1978) however the large winter aggregation recently discovered off NJ (Nesslage et al. 2026) suggest a northward shift that could change arrival times in Atlantic estuaries. Menhaden peak abundance in Narragansett Bay based on spotter data has shifted to later in the year from 2008 to 2026 at the rate of 2.33 (SE=0.78) days per year or a total of 6.3 weeks. With regard to osprey, Solonen 2008, Sullivan et al. (2016) and Therrien et al. (2017) found earlier spring migrations under climate change, a phenomenon common in north American migratory birds writ large (Horton et al. 2020, Neate-Clegg et al. 2024). Asynchrony in menhaden occurrence and osprey migration could create Cushing-like trophic mismatches, causing food stress absent an overall stock decline in menhaden. Interestingly, osprey fall migration timing along the Atlantic coast (Therrien et al. 2017) and interior US (Steiner et al. 2022) has not changed. These findings suggest a longer occupancy of and foraging demand on the breeding/fledging grounds.

Widespread deployment of manmade structures, including those dedicated to osprey, is likely to have exacerbated the above problems. In a May 2025 letter to the US House of Representatives, the United States Geological Survey (USGS) director stated explicitly that "populations cannot grow indefinitely because the resources they depend on are finite" and that "nesting structures are now at surplus". This ecological axiom suggests a growing disconnect between burgeoning osprey populations and their food supplies. Figure 11 shows that menhaden abundance since 2020 has been slightly less than from 1990 to 2000 when exponential growth in osprey was occurring (Watts et al. 2004). Osprey have benefitted greatly from deployment of artificial nest structures (Bierregaard et al. 2014, Poole 2019, Petersen et al. 2020) where productivity is often higher than at natural sites (Canal et al. 2018, Airola and Estep 2022). I note that carrying capacity (K) and intrinsic rate (r_m) are not independent parameters in logistic population dynamics. A review of Verhulst's derivation of the logistic equation reveals they are positively related through the strength of density dependence or $r_m=K*\beta$ (Marschall et al. 2023). In territorial raptors, K has both physical (nests) and energetic (food) components i.e. $K=K_1*K_2$. Either component can be limiting (Newton 1988, Monzon and Fredenberg 2018). The dynamic is powerfully demonstrated in new reservoirs where both the physical (flooded trees) and energy (new fish population) needs of ospreys are simultaneously provided (Henny 1978). Another example is in kites (*Milvus sp.)* where anthropogenic food augmentation for cultural reasons allows kites to fully utilize nest sites (Kumar et al. 2019, Nageli et al. 2022). Food supplementation is most effective in marginal habitats colonized later in population recovery i.e. an ideal despotic distribution forms (Lohmus 2011, Ferrer et al. 2017). This knowledge is not new. A century ago, RI

farmers around Mt. Hope Bay erected nesting poles next to their fishy farm ponds. They were occupied by ospreys that in turn chased away chicken hawks (Poole 2019). Substitution, rearrangement and analysis of the Verhulst formulation show that if nest sites increase but food supply does not, offsetting adjustments to r_m (decrease) or β (increase) are needed to balance the Verlhulst differential equation. Watts et al. (2026) recently reported on widespread reproductive failure in osprey but dismissed density dependent factors. They acknowledged increased placement and use of artificial nesting structures as having reduced mammalian predation but did not contemplate the link of carrying capacity and intrinsic rate. The authors know that structures have proliferated in the Bay region (Watts and Paxton 2007). Their logic that osprey cannot deplete or control their food supply is theoretically wrong on the 1st count and irrelevant on the 2nd. Unless the menhaden taken by osprey are continuously replaced, depletion surely occurs albeit at a lower rate than by fishery. It is not clear what they mean by "control" but regulation of menhaden population size manifests beyond Chesapeake Bay. It seems they have not considered the possibility of a structure induced overshoot, outstripping a static food supply. Territory size is inversely related to food supply in raptors so density dependence should emerge when density exceeds food supply (Sells and Mitchell 2020). A new population in Spain "stabilized" or reached capacity just 13 years after reintroduction (Garcia-Macia 2026). A despotic free distribution resulted in a recovering Estonian population where osprey 1st utilized prime nesting sites followed by inferior sites such that average reproductive success declined (Lohmus 2001).

Clearly, artificial structures have elevated the physical component of osprey habitat and what was once an adequate food supply may no longer be so. This is formalized in the resource tracking hypothesis (Lack 1954, Bizberg-Barraza 2024). Birds with altricial young may produce an excess which only survives when resources allow. Siblicide improves prospects for remaining raptor progeny (Simmons 2002). A natural osprey progression could be; add attractive structures, cause transition of floaters to breeders, overload the food supply, engage asymmetric brood reduction, and finally capable but energy deficient birds cease reproduction altogether. To wit, Watts et al. (2026) observed an order of magnitude increase in non-breeders (27%) in 2024. Similarly, preliminary 2026 ASRI data show that 24% of nesting pairs abandoned their nests (S. Brown, ASRI- pers. comm.). Capable raptors, declining to breed, is known as the 'acceptance threshold' and occurs under extreme food stress even in generalist species (Rutz and Bijlsma 2006). It is believed to be a trade-off between cost/benefit of current reproduction vs survival for long-term reproduction. Habitat provisioning is not always beneficial to territorial birds as it can create ecological traps (Mainwaring 2015) when site selection is not matched with site quality (Bai et al. 2009). Artificial structures can lure low food demand floaters and convert them into high food demand breeders (Bjorklund et al. 2013). This typically happens when structure placements are; at odds with a limiting resource distribution (Martin et al. 2005), are near hazards (Murphy et al. 2024) or are otherwise unsuitable (Watchorn et al. 2023). Watt et al. (2026) dismissed increasing floater (non-breeder) interference but present no data on this population component. Interference is a well-known and critical component of raptor population dynamics (Bretagnolle et al. 2008, Wahl and Barbraud 2013, Penteriani et al. 2015) and has been observed in sympatric Chesapeake Bay eagles (Turrin 2014). Floating components of bird populations are revealed when additional habitat is provided (Ainley 2024). There is compelling evidence of an osprey food shortage but it may be that the egg came before the chicken i.e. added structures have spurred osprey numbers more than their food supply.

Florida Case Study- Figure 13 shows the FL series with the usual logistic model fit. The intrinsic rate of increase was estimated at 0.057 (SE=0.004). I note that the three bursts of growth showed a much faster rate, averaging 0.18. K was estimated at 3.09 survey units (SE=0.55). The overall trend is near linear but with a sinusoidal pattern superimposed. There is clear autocorrelation in the residuals with a low-frequency, decadal period. A maximum negative correlation occurred at lag 10 ($r=-0.67$, $df=42$, $P<0.01$). The wavelength (20 yrs) approximates the species lifespan. Tringali (2023) noted that the FL abundance increase and inland range expansion were associated with provision of artificial structures and reservoir construction suggesting increased carrying capacity. Presence of a sinusoidal residual

pattern is present in the US and RI trend albeit lesser in amplitude (Figures 1,4). Relevance to RI is that FL osprey have experienced multiple episodes of population contraction followed by expansion. RI osprey (and others) may have entered a contraction phase. The pattern in Figure 13 may represent waxing and waning of the floater pool as shown for Bonelli's eagles by Badia-Boher et al. (2025). In the FL scenario, discrete upgrades in habitat would draw from the floater pool for colonization, temporarily depleting it and suspending further growth in nesting pairs until the pool refilled. Unfortunately, no information is available for this crucial population component in RI osprey however the geographic expansion is clear (Dark and Clarkson 2023). An intriguing possibility is that the mathematics of traffic flow i.e. the inch worm effect (Wen et al. 2023) or laminar-turbulent flow transitions (Stokes 1851) could be used to analyze this pattern in osprey. In both cases, flow variance (distance per time) is a key initiating factor. This might be reinterpreted as density variance (number per time) between osprey breeding and floating population components.

Management Recommendations- A study of menhaden and osprey was recommended by the ASMFC and has been approved and funded by the Virginia legislature in their 2026 session. Hopefully, it will provide some sorely needed answers. In the interim, menhaden management should emphasize sequencing fishery harvest to follow, not overlap, the period in the osprey breeding season where energetic demands are at maximum. Newly hatched osprey follow a sigmoidal growth pattern in weight, achieving 90% of the asymptote in 32-37 days (Stinson 1977, Poole 1989, Schaadt and Bird 1993). Survival and energetic studies indicate that days 11-16 (before the inflexion point) are critical (Ricklefs 1974, Hagan 1986, Academia and Watts 2023). These findings argue for a 2–5 week buffer between fledge provisioning and menhaden harvesting that would be a precautionary action. An interesting parallel exists in the Southern ocean where concentrating commercial krill fishing may be limiting great whale foraging and recovery. Space-time separation strategies have been recommended (Savoca et al. 2024). In addition to fishery regulation, osprey managers should cease provision of artificial nesting structures in areas with static food supplies. Continued deployment will further activate the largely benign floater pool without additional food to sustain it triggering more brood reduction. I close by observing that brood reduction is a natural process that is widespread in avian species, known at least since the time of eminent ornithologist David Lack.

Conclusions-

1) Rhode Island ospreys were nearly extirpated following DDT use, declining to only 6 breeding pairs in 1972. DDT was a lethal factor reducing fledgling production to just 23% of that needed for population sustainability.
2) RI Population recovery has occurred at a rate of 0.077 per year since 1977 reaching 302 nesting pairs in 2025. Although a decline may have occurred in 2026, the population is still considerably larger than in the 1940's prior to DDT usage. The RI recovery is part of a nationwide trend with the US population increasing at 3.9% per year since 1966.
3) RI osprey reproduction has been good averaging 1.35 fledglings per breeding pair long-term although very recent estimates are lower and should be monitored. Projections indicate a 16% decline in nesting pairs under continued low reproductive success.
4) Ospreys have low intrinsic rates of increase compared to other birds and animals because of low fecundity and delayed reproduction, emphasizing the importance of adult survival and longevity.
5) First signs of density dependent regulation are emerging in RI although increased use of artificial nesting structures and their effect on carrying capacity needs more study. Food supply limitations are occurring in other osprey populations and should be monitored in RI.
6) The RI data set and conspecific knowledge has matured enough so that a spatially explicit, state-space, integrated modeling effort can be attempted including the cryptic floater component.
7) RI osprey reproductive success is positively correlated with a local index of menhaden abundance with the correlation growing stronger in recent years. Low reproductive success in recent years is coincident to a decline in spotter pilot menhaden school counts in Narragansett Bay.

8) There are several inconsistencies in the menhaden-osprey relationship that need clarification. A chicken and egg conundrum is presented between not enough menhaden or too many osprey. The available data indicate a growing mismatch between osprey and their food supply in marine waters that is progressing from south to north.
9) Because of divergent phenologies, prosecution of the menhaden fishery should be separated in space and time from the critical period of osprey food provisioning. In addition, deployment of artificial osprey nesting structures should cease unless new food supplies are provided.

Conflict of Interest Statement-

The author received no compensation and declares that he has no competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgements

I dedicate this research to my wife, Lori, who served the state as a wildlife biologist for decades. Her knowledge of osprey life history and behavior was essential to my education. Among her many responsibilities was rebuilding the RI osprey population. She spent many a summer day counting and observing ospreys as well as assembling and installing nesting structures. She was (and is) ever ready to assist a constituent or parties with problem birds. Woe was the party that messed with her birds. Today, she smiles whenever we see an occupied pole or spies fishing ospreys at my favorite spot. Birders everywhere along the flyway are in her debt. I thank Lincoln Dark and Drs. Sarah Deckel and Sydney Brown of the Audubon Society of RI for sharing their data and insights with me. The ASRI has done yeoman's work having taken over the project after Lor's retirement. Finally, I thank my higher power, the spark of nature, for this magnificent bird and the sobriety to study it.

Appendix - Atlantic Menhaden Stock and Recruitment and Potential Population Size

The issue of osprey reproduction and menhaden abundance begs the question of how much menhaden there can be under current fishery and environmental conditions. As noted above, restoring the historical ratio of coastwide or local menhaden to osprey would require a massive increase in menhaden or a reduction in osprey numbers. The latter is unlikely to be a serious policy objective but the birds may accomplish it on their own through brood reduction. The historical analysis of Ervin et al. (2026) using stock reduction analysis suggest a maximum menhaden biomass of about 4,000 KT in 1880. Uphoff and Sharov (2018) used a Steele-Henderson production model applied to modern data and estimated an unfished biomass of 3,950 KT. To evaluate the current potential for menhaden population growth, I analyzed the relationship between menhaden abundance and resulting recruitment using the ASMFC (2025) BAM assessment results. Specifically, I used the 1955 to 2023 estimates of population fecundity (trillions) and recruitment (billions). I included the AMO climate index given the studies indicating its wide influence on the marine production systems (Edwards et al. 2013) and menhaden specifically (Buchheister et al. 2016, Midway et al. 2020). As noted above, the index has been in a positive phase for two decades but was in negative phase during the early portion of the menhaden assessment period. Annual AMO, unsmoothed data was accessed at the NOAA climate/weather website (Figure A1). Following Nelson et al. (1977) and Vaughann and Merriner (1991), I fit a Ricker type stock recruitment model including the AMO as a covariate:

$$R_t = \alpha * S_t * \exp(-\beta 1 * S_t + \beta 2 * A_t) \qquad (1)$$

where: R= recruitment in billions

S= population egg production in trillions eggs

A= the AMO index as deviations from long-term mean

α= alpha slope at origin

β1= strength of density dependence

β2= AMO effect parameter

t= year.

Eq. 1 was fit to the data using Excel Solver with parameter uncertainty evaluated with the jackknife method.

Figure A2 shows the S-R data plot along with the estimated climate-dependent model. Population fecundity varied by approximately 5-fold with a maximum of 2.55 trillion in 1955. With the exception of the extraordinary 1958-year class, recruitment has varied between 13 and 80 billion fish. Alpha was estimated at 115.72 (SE=13.11) while beta was estimated at 1.014 (SE=0.101), both significantly greater than zero. Note that these estimates may differ in absolute value and scale from past results depending on S-R units used and the natural mortality rates specified in the assessment. The AMO parameter was negative at -0.0066 as expected but not significantly different from zero (95% CI -0.234 to 0.221). Although NS here, other analyses support a negative effect including lags (Deyle et al. 2018). Higher larval survival was associated with a negative AMO phase in Simpson et al. (2016). Surplus production modeling in Drew et al. (2021, Fig.4) shows a decline in menhaden intrinsic rate coincident to the AMO shift to positive phase. Growth of age 1 menhaden was found inversely correlated with the AMO (Midway et al. 2020). The reciprocal of beta corresponds to the fecundity resulting in maximum recruitment. It was estimated at 0.961 (SE=0.077) trillion eggs. Menhaden were last assessed at 1.24 trillion eggs in 2023 and more recent index data suggest it is less than that (ASMFC 2026). The over compensatory curve in Figure A2 suggests two things. First, fecundity is trending toward the 1/β point where the probability of good recruitment is higher, the outlier 1958-year class notwithstanding. Second, the dome-shaped S-R curve projects very low recruitment under the large fecundity increase needed to restore the

menhaden/osprey ratio. Further, Vaughan and Merriner (1991) reported a range for maximum sustainable yield (MSY) for Atlantic menhaden of 370 to 570 KT at a fishing mortality rate (F_{msy}) of 0.47. Since the fishing mortality rate at MSY is ½ the intrinsic rate of increase, carrying capacity or unfished biomass in the legacy production models is only K= ($4*MSY/r_m$) or 1,574 to 2,426 KT. Current fully recruited F rate is about 0.20 under a total kill of 200 KT (ASMFC 2025). This represents a great reduction since the late 1960's when F reached 0.95 (Dryfoos et a. (1972). The assessment team has only presented short-term projections of overfishing risk to date. However, the current F and retrospective stock performance suggest some population growth above 1,900 KT is possible with a limit of about 3,400 KT but only following extraordinary year classes as in 1955 and 1958. To summarize, there is no evidence now or in the historical record that menhaden stock size can grow to a magnitude where the existing Chesapeake Bay osprey population (and others) have the same food availability as during the 1970's recovery of the predator and prey. That would require more than a quadrupling of menhaden biomass to over 7,000 KT. Reference to Figure A2 shows that level in a high AMO phase is unlikely.

Watts et al. (2024) used the ASMFC coastwide YOY index in their calculations which in turn was criticized by Latour et al. (2024). The mismatch between YOY menhaden length and preferred osprey prey size notwithstanding, a potent criticism was that YOY indices "do not accurately reflect the abundance of age 1 and older fish and therefore are not a reliable proxy for the abundance and availability of menhaden". Uphoff (2003) demonstrated a good correlation between the MD component to the YOY index and age 0 abundance estimates from the operational catch at age assessment. However, substantial modifications have been made to the assessment model, including the natural mortality rate that drove hindcasts of age 0. Moreover, YOY shifting between index regions has occurred (Buchheister et al. 2016). To examine this further, I accessed the 1959-2023 coastwide YOY index from ASMFC (2025) and compared it to the BAM recruitment estimates via regression analysis. Linear models indicated a positive y-intercept implying nonsensical spontaneous generation of recruits at zero YOY. A power function through the origin made more sense and is shown in Figure A3. The correlation is weak with only 16% of the variance in recruitment explained by YOY. More importantly, the slope (b=0.161, SE=0.035) to the power function is significantly less than 1.0. This indicates strong hyperstability in BAM recruits. Putative YOY could decline to near zero, without much change in recruitment. Love et al. (2006) explained this with a shift in Chesapeake Bay YOY production from northern to southern Bay tributaries. Moreover, YOY were negatively correlated with BAM population fecundity at lag zero (r=-0.60, Fig. A4). Since the fitted Ricker S-R curve in A4 must originate at zero, externe overcompensation is suggested i.e. steepness (h) approaches 1.0. This was also apparent in early S-R data in Ahrenholz (1987) where obsolete VPA approaches used constant M= 0.45 in the analyses. In that study, good recruitment was evident at only 6% of maximum egg deposition. A mechanism this strong is generally unlikely (Mangel et al. 2009) and hard to explain in menhaden given a life history which was recently shown to be "slower" than heretofore thought (Ault et al. 2026). In support, Simpson et al. (2016) showed that oceanic larval menhaden abundance was correlated (r=0.56) with BAM assessed spawning biomass but the larvae did not translate through to YOY. They struggled to explain an apparent decline in larval survival with density dependence and environmental factors. More likely YOY survey abundance is not reflective of recruitment to the stock but more the vagaries of larval supply to the sampled estuaries (Love et al. 2006, Houde et al. 2016, Simpson et al. 2017). I concur with Latour et al. (2024) that the YOY index was not a good metric of osprey food availability in Watts et al. (2024). That is not to say that food supply, including menhaden, has not been limiting in Chesapeake Bay and elsewhere. A spatially stratified BAM assessment will be needed to show that.

Subject: [External] Addendum 1 Comment for the Public Record

Dear Sir:

I support Addendum II and the most restrictive options.

The future of our wildlife must be protected and preserved, and if not now, when! There must be at minimum, a 50% reduction in the overfishing of menhaden. No additional studies are needed. It is time to act.

Sincerely,
Brian Goldstein

Subject: [External] Support for Atlantic Menhaden Conservation (Draft Addendum II)

Good morning, Mr. Boyle:

As a devoted advocate for the health of our coastal waters and the daughter of two residents of Reedville, Virginia, I am writing in fervent support of stronger conservation measures under the Atlantic States Marine Fisheries Commission's (ASMFC) Atlantic Menhaden Draft Addendum II. I vigorously support the approval of a 50% reduction in the Chesapeake Bay reduction fishery cap and establish seasonal quota periods.

Atlantic menhaden are a foundational forage fish. Ecologically, they are critical to the survival of sportfish like striped bass and blue fish, as well as avian predators like ospreys, which are currently suffering from historic nest failures and starvation due to localized food depletion. In addition, an over-concentration of industrial reduction fishing by Ocean Harvesters/Omega Protein has devastated local bait watermen and small-scale commercial operations who rely on stable menhaden populations.

The current industrial cap of 51,000 metric tons allows a highly centralized fleet to extract massive quantities of this ecological anchor from sensitive nursery grounds. Implementing a 50% cap reduction and spreading the remaining harvest evenly across the season will protect the broader Atlantic marine ecosystem and support the coastal economies tied to recreational fishing and tourism.

Thank you for the opportunity to submit these comments in support of protecting our vital public marine resources.

Sincerely,
Caitlin Gritt

10/4/26

ASMFC Menhaden Board,

Regarding Atlantic Menhaden Draft Addendum II, my comments are as follows:

I am an avid saltwater fisherman who fishes 50-75 times a year out of Barnegat Inlet, NJ. I fish anywhere from Sandy Hook to Holgate and as far east as the canyons. I have been out on my boat more than 50 times already this year and I have not seen a single school of adult bunker. In fact, they have been declining for the last several years and that has caused much poorer fishing, especially for striped bass. Gone are the days when I used to regularly see National Geographic moments, bass, whales and other predators spraying bunker with gannets and seagulls diving into the fray. We have a serious problem here and you need to take action to correct it.

Reduction fishing for menhaden should not be allowed at all. I hear about how that would hurt all those who work for Omega Protein. However, you must consider the negative economic impact that is being caused by the lack of bunker. Private, charter and party boats are taking less trips due to the lack of fish. Tackle stores, marinas, motels and other businesses that depend on fisherman are also suffering. However, it's not just the fishing sector that is suffering, it's those who enjoy bird and whale watching as well. Whales may have moved to other areas seeking alternative food sources, but they certainly miss eating bunker. However, shorebirds, particularly ospreys have been dying off and failing to nest successfully.

There are many factors that the ASMFC cannot control that are negatively affecting our fisheries and environment. However, this issue is one that you can control and therefore I urge you to take most restrictive action possible. **The coastwide TAC must be decreased significantly** but specifically regarding this addendum, please vote in favor of the following options:

- **Bay Cap Amount: Sub-Option B4** - a **50% reduction**, resulting in a **25,500 mt cap**.
- **Quota Periods: Option B1** - even-length periods with evenly distributed harvest.
- **Quota Period overage/underage payback: Option B** - payback and rollover.
- **Underage Provision: Underage Sub-Option 1** - roll Period 1 underage evenly into Periods 2 and 3.
- **Revisit Provision: Option B** — revisit the Bay Cap every three years.

Sincerely,

Paul M. Haertel

Subject: [External] atlantic menhaden Draft Add II

I am very concerned about the lack of science, and conscience of the overfishing of menhaden. not only does it affect marine life, those who rely on this for employment, but its also very detrimental to avian world. Osprey in NJ have a terrible nest failure with either only one egg viable, to the nests being abandoned and the young Ospreys dying of starvation. there isn't enough focus on the plight of the Osprey especially since we joined as a nation to return that balance due to DDT deaths.

please fight for less harvesting or a year moratorium on menhaden for everything that relies on it for life

Nancy Hart

October 2026

Dear Members of the Atlantic Menhaden Management Board:

I am a Virginia resident living in Middlesex County near the southern end of the Chesapeake Bay. I am a boater, recreational angler, oyster gardener, and conservation advocate. I spend considerable time on and near the Bay and have a strong personal interest in protecting its ecological health and the public resources upon which its wildlife, fisheries, businesses, and communities depend. I appreciate the opportunity to comment on Draft Addendum II.

I strongly support and urge the Atlantic States Marine Fisheries Commission to adopt the most protective alternatives available under Draft Addendum II, including the following specific measures:

1. **Section 3.1, Option C, including Sub-option C1e**, setting the Chesapeake Bay reduction fishery cap at 13.6% of the coastwide Total Allowable Catch, initially resulting in a cap of 25,500 metric tons, a 50% reduction from the current cap.
2. **Section 3.1, Sub-option C2a**, establishing a 51,000-metric-ton upper limit with no lower limit.
3. **Section 3.2.1, Option B, Sub-option B2**, establishing three quota periods with allocations of 25%, 25%, and 50%.
4. **Section 3.2.2, Option B**, requiring quota-period overage payback and providing for in-year rollover of unused quota.
5. **Section 3.2.2, Underage Sub-option 1**, dividing unused Period 1 quota equally between Periods 2 and 3.
6. **Section 3.3, Option B**, requiring the Commission to revisit the Bay cap every three years following implementation.

I. A 50% Reduction Should Be the Minimum Protective Action

The current Chesapeake Bay reduction fishery cap is 51,000 metric tons. Section 3.1, Option C, including Sub-option C1e, would initially reduce the cap to 25,500 metric tons and link it to a fixed proportion of the coastwide Total Allowable Catch. This is the largest reduction presented in Draft Addendum II, and the Commission should adopt it without a multiyear phase-in.

The current Bay cap is not based on a scientifically determined estimate of the forage needs of Chesapeake Bay predators. Rather, it was derived from historical harvest levels. While historical harvest data are informative, they do not establish that such harvest levels were ecologically sustainable or that they left sufficient menhaden available to support predators and other fisheries throughout the Bay.

The central weakness in the arguments that support the current data is the assumption that coastwide population status adequately reflects conditions with the Chesapeake Bay. Coastwide stock status dos not resolve Chesapeake Bay concerns, and shouldn't be used to conclude that current harvest levels are harmless or that further reductions are unnecessary.

II. Coastwide Assessments Have Significant Scientific Limitations

For years, local fishermen, boaters, birdwatchers, conservation organizations and scientists have raised concerns that intensive harvests can reduce local availability of menhaden even if coastwide metrics appear healthy. The very existence of the Chesapeake Bay cap reflects past recognition by the Commission that localized depletion is a legitimate management concern. In short, coastwide stock status does not answer the central question before the Commission: whether sufficient menhaden remain available within the Chesapeake Bay to fulfill their ecological role.

Draft Addendum II explicitly acknowledges that sufficient scientific information is not presently available to comprehensively characterize the abundance and distribution of menhaden throughout the Chesapeake Bay or the influence of fishing pressure on Bay-specific menhaden availability.

The coastwide TAC and the Chesapeake Bay cap serve different purposes. The coastwide TAC addresses coastwide stock status. The Chesapeake Bay cap was created because the Bay is a critical nursery area and because of longstanding concerns regarding localized depletion. These concerns remain relevant today.

Accordingly, a determination that the coastwide stock is not overfished should not be interpreted as proof that current harvest levels within Chesapeake Bay have no localized ecological impacts.

III. Recent Ecological Indicators Support Precautionary Action

Scientific uncertainty is not evidence that current harvest levels are harmless. It is a reason to manage cautiously, particularly where the resource is an important forage species and fishing effort can be concentrated geographically and seasonally.

Draft Addendum II reports that more than 50% of Chesapeake Bay reduction-fishery landings occurred during a six-week midsummer period in both 2023 and 2024. The Commission states that such concentrated harvest may affect the availability of menhaden to predators and other fisheries.

The draft also documents:

- A 60% decline in Maryland Chesapeake Bay pound-net harvests in 2024 compared to the 2018-2022 average.
- Declines in pound-net catch-per-unit-effort in Maryland, Virginia, and Potomac River Fisheries Commission waters.
- Reduced catch rates in Maryland during the latter portion of 2024.

- A substantial decline in a fishery-independent menhaden index in Maryland's Choptank River beginning in 2024.

While these observations do not prove that the reduction fishery caused these changes, or eliminate other potential explanations. They do demonstrate that substantial uncertainty exists and that the possibility of ecological impacts cannot be dismissed.

The appropriate response to uncertainty in the management of a foundational forage species is caution, not delay.

IV. Seasonal Quotas Should Limit Concentrated Harvest

I support **Section 3.2.1, Option B, Sub-option B2**, allocating 25% of the Bay cap to the first quota period, 25% to the second period, and 50% to the third period.

This option places greater emphasis on delaying harvest until later in the season, reducing the risk of concentrated removals during critical spring and summer periods when predator demands may be greatest.

I also support **Section 3.2.2, Option B**, which requires overage accountability. Seasonal allocations will be meaningful only if harvesters are held accountable for exceeding them.

Likewise, I support **Section 3.2.2, Underage Sub-option 1**, which distributes unused first-period quota between the second and third periods rather than concentrating all unused quota into the final period.

V. Osprey Reproduction Provides an Important Ecological Warning

Atlantic menhaden are among the Chesapeake Bay's most important forage species. They are a critical food source for striped bass, bluefish, red drum, cobia, ospreys, and many other predators.

A recent peer-reviewed study monitored 571 osprey nests across the Chesapeake Bay and found widespread reproductive deficits in high-salinity portions of the Bay. The researchers observed greater food stress, higher nest failure, and reduced reproductive success in these areas and suggested that reduced availability of Atlantic menhaden may be a primary driver of those patterns.

While this study does not establish that reduction fishery caused these deficits. It does, however, document significant ecological concerns that deserve serious consideration.

The Commission need not wait until every cause-and-effect question is resolved before taking action to reduce a known and manageable source of risk.

VI. The Commission Should Not Delay Protection While Additional Research Proceeds

Additional Chesapeake Bay-specific research is clearly needed, and I strongly support efforts to improve understanding of menhaden abundance, distribution, and ecological function within the Bay. However, the Commission should not postpone precautionary management while new studies are being developed, conducted, analyzed, and incorporated into future management decisions.

Maintaining current harvest levels during a period of acknowledged uncertainty is itself a management choice. Waiting for perfect information is not a prudent management strategy when substantial uncertainty already exists. The precautionary principle indicates that management should reduce risk while new information is being gathered.

The better course is to reduce the cap now, manage harvest more conservatively, continue collecting better data, and revisit management decisions as improved science becomes available.

For this reason, I strongly support **Section 3.3, Option B**, requiring the Commission to revisit the Chesapeake Bay cap every three years.

VII. Menhaden Are a Public Resource

We constantly hear about the economic impacts on the Reedville menhaden industrial processing facility if any reductions or restrictions are imposed. But, other associated business impacts pale in comparison and deserve equal consideration.

Atlantic menhaden are a **public trust resource managed for the benefit of all users and the ecosystem itself, not any single company or industry sector**. They are often called the most important fish in the sea because they serve as a critical forage species for numerous predators.

The Commission must also consider the broader public benefits supported by healthy menhaden populations, including:

- Recreational fishing;
- Charter fishing businesses;
- Tourism;
- Boating;
- Waterfront communities;
- Wildlife viewing;
- Predator-dependent commercial fisheries; and
- Countless other economic activities linked to a healthy Chesapeake Bay ecosystem.

The economic analyses summarized in Draft Addendum II primarily evaluate impacts on the reduction and bait fisheries. They do not constitute a complete valuation of the Bay's broader

ecological and economic interests. The benefits generated by abundant menhaden and a healthy ecosystem extend far beyond the balance sheet of a single industrial fishing company. Atlantic menhaden are a foundational forage species and a public resource. Their value extends far beyond their value as fish meal and fish oil. Management decisions should therefore prioritize the long-term health of the Chesapeake Bay ecosystem and the broad public interests and benefits derived from it.

VIII. Conclusion

For these and the other reasons cited above, I urge the Commission to **adopt the following management measures to protect the long-term health and resilience of the Chesapeake Bay ecosystem:**

- Select **Section 3.1, Option C, including Sub-option C1e**;
- Select **Section 3.1, Sub-option C2a**;
- Implement the 50% reduction without a phase-in;
- Select **Section 3.2.1, Option B, Sub-option B2**;
- Select **Section 3.2.2, Option B**;
- Select **Section 3.2.2, Underage Sub-option 1**;
- Select **Section 3.3, Option B**; and
- Continue developing Bay-specific science while managing conservatively in the face of uncertainty.

The Chesapeake Bay is one of the most important estuaries in North America. When uncertainty exists regarding a critical forage species, the prudent course is to protect the resource while additional science is developed.

Thank you for considering my comments.

Respectfully submitted,

Tracy Heinzman
Hartfield, VA 23071

Subject: [External] MENHADEN & THE ATLANTIC MENHADEN DRAFT ADDENDUM II

To the Members of the Atlantic States Marine Fisheries Commission.
comments@asmfc.org

As a Member of the Great Bridge Fisherman's Association, of Chesapeake, Virginia
I would like to see these Options adopted from **The Atlantic Menhaden Draft Addendum II**

3.1 Chesapeake Bay Reduction Fishery Cap Amount
Support option C1e: that reduces the CAP by at least 50 percent in 2027 and limits the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).
Also, support option C2a, which sets an upper limit of 51,000mt for the Bay Cap (the current level).

3.2 Chesapeake Bay Cap Distribution
Support option B2, which establishes three even length quota periods for the Bay Cap, but distributes harvest 25% in period 1, 25% in period 2, and 50% into period 3.
Also, support option B, which establishes quota period overage and underage provisions within a fishing
year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Support Option B to revisit the Bay Cap every 3 years.

The over harvesting of Menhaden in The Chesapeake Bay is finally getting support from a broader audience. Please support the options listed above to allow the Menhaden population to increase and to provide food for the species that count on them in and around Chesapeake Bay. ***Save the Menhaden & Save the Bay***

Thank you for your attention to this matter.
Sincerely,
Tom Herendeen, Concerned Citizen,
Working & Living on and around the BAY since 1976

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

⭐ FINAL UNIFIED PUBLIC COMMENT PACKAGE
Atlantic Menhaden Draft Addendum II
Submitted October 7, 2026

To the Atlantic Menhaden Management Board,

Thank you for the opportunity to comment on Draft Addendum II. My connection to coastal ecosystems began in childhood. I saw my first osprey at age five while fishing at Forge Pond in Brick, New Jersey, and I remember wondering why they suddenly disappeared during the same years our neighborhood in Birchwood Park was being sprayed for mosquitoes. It wasn't until my first Earth Science class that I learned about DDT and understood what had happened to the ospreys I grew up watching. I have been a shore girl with sand in my shoes ever since, and that lifelong connection to coastal wildlife is why the current concerns about forage availability resonate so strongly with me.

The information presented in Draft Addendum II is deeply concerning. The document states: "Recent observations… suggest that availability of menhaden in Chesapeake Bay may be changing."

This is not theoretical. In 2023 and 2024, we saw clear, measurable impacts:

• Maryland pound net harvest declined 60% in 2024.
• CPUE dropped sharply across Maryland, PRFC, and Virginia.
• Independent surveys (Choptank River) show menhaden abundance collapsed in 2024 and remained low in 2025.
• Predators such as striped bass, bluefish, weakfish, and osprey are already experiencing stress.

These indicators point to a forage shortage with ecosystem-wide consequences.

⭐ Menhaden as Filter Feeders — Water Quality Matters

Atlantic menhaden also play a critical role in maintaining water quality. As filter feeders, they help remove excess nutrients and particulate matter from coastal waters, improving clarity and reducing the risk of harmful algal blooms. Protecting menhaden abundance is not only about supporting predators; it is also about preserving the water quality that sustains the broader Chesapeake and coastal environments.

⭐ Documented Predator Impacts: Barnegat Light Osprey Nest (2023)

As a former moderator for the Barnegat Light Osprey Cam, I witnessed a severe food-stress event at the nest during the 2023 season. The first-hatched chick remained alive while her nestmates died during extended periods without fish deliveries. The adult female, Daisy, ultimately removed the deceased chicks and carried them to Barnegat Bay. This was a timestamped, publicly accessible example of how forage shortages directly affect predator survival and reproductive success.

⭐ Four Consecutive Years of Osprey Reproductive Failure (2023–2026)

From 2023 through 2026, the Barnegat Light Osprey Cam documented four consecutive seasons of reproductive failure, each coinciding with periods of reduced forage availability. In 2023, two of the three chicks starved to death during extended gaps between fish deliveries, and only one fledged successfully. In 2024, although Daisy and Duke continued their long-term pair bond, Daisy was unable to lay eggs despite multiple successful meetings. In 2025, Duke bonded with a new female after Daisy did not return; she laid three eggs, but a nor'easter and limited fish availability forced her to leave the nest to feed, allowing a gull to take two eggs while the third deteriorated in the elements despite Duke's attempts to incubate it. In 2026, several females visited the nest, but none remained, and Duke spent the season as a bachelor.

These four years of consecutive reproductive failure illustrate how forage shortages — especially when reduction harvest is concentrated into short, high-intensity periods — can affect predator behavior, nesting success, and overall ecosystem stability. While multiple environmental factors influence osprey reproduction, the timing and availability of menhaden remain central drivers, consistent with the concerns outlined in Draft Addendum II.

⭐ Recreational Fishing Impacts

My family has fished in New Jersey waters for generations. Between my brother and me, we have caught only one striped bass in recent years — unprecedented in our decades of experience. Despite using adaptive equipment that allows me to fish from party boats in my electric wheelchair, the lack of striped bass encounters has been unmistakable.

⭐ Family Crabbing Traditions

My niece and nephew grew up crabbing in the same places our family has used for generations, and in recent years they have asked why the crabs are no longer showing up in the traps the way they used to. Their children even asked whether the crabs are “really going to eat chicken now”, reflecting the confusion many coastal families feel as familiar patterns disappear.

⭐ Tourism, Water Quality & My Summers on the Boardwalk

During the summers of 1977 through 1979, I worked as a lifeguard at the Casino Pool in Seaside Heights. After the pool closed at 4:00 PM, I helped run the Ocean Peak restaurant and the fishing pier on the Casino Pier. Those summers made it clear how closely water quality, fishing success, and tourism are linked.

⭐ Volunteer Work at the Barnegat Light Osprey Cam

After my accident, I found new ways to stay involved in coastal conservation. One of the most meaningful opportunities came when Ben Wurst trusted me to take over as the moderator (“Beach Girl”) for the Barnegat Light Osprey Cam after our first moderator, Twist, passed away in 2021. Moderating the cam allowed me to contribute directly to public education and wildlife observation.

⭐ Continued Osprey Monitoring & Educational Outreach

Although I no longer moderate the cam, I remain an active supporter of the Barnegat Light community. I continue watching the nest, sharing video clips and screenshots, and preparing educational content for the YouTube channel I am building.

⭐ Terrapin Nesting Project & Mosquito Ditch Habitat Impacts

I am also an active supporter of the Terrapin Nesting Project on Long Beach Island. The Barnegat Light marsh beneath the Osprey Cam contains mosquito ditches created in the 1930s that now serve as vital terrapin habitat. Since 2019, viewers have watched female terrapins emerge from the bay, travel through the marsh barrier, cross Bayview Avenue, and enter a protected nesting area.

⭐ Winter Waterfowl & Marsh Wildlife Observations

The Barnegat Light marsh supports a diverse wintering population of Atlantic Brant, ducks, geese, herons, and red foxes. These species depend on the same interconnected system of marsh hydrology, forage availability, and water quality that supports menhaden, terrapins, and osprey.

⭐ Winter Predator Interactions: Bald Eagle Pursuit (Feb 13, 2023)

On February 13, 2023, a young Bald Eagle pursued a diving duck across the marsh. The chase was recorded and shared publicly, illustrating the complexity of winter marsh dynamics.

⭐ Raptors & Marsh Predators Observed at Barnegat Light

Regularly observed species include Bald Eagle, Northern Harrier, Cooper's Hawk, Belted Kingfisher, Green Heron, Black-crowned Night Heron, and American Bittern.

⭐ Shorebirds, Wading Birds & Diving Ducks of Barnegat Light

Regularly observed species include Piping Plovers, Yellowlegs, Black Skimmers, American Oystercatchers, and diving ducks such as scoters, bufflehead, and mergansers.

⭐ Marsh Mammals & Predator Behavior

The marsh also supports small mammals such as marsh rats. One notable observation involved a Great Egret capturing a marsh rat and dunking it repeatedly to exhaust it before swallowing it whole.

⭐ Ecological Richness of the Barnegat Light Osprey Cam Area

Fish delivered to the nest provide a real-time record of forage availability, including menhaden, bluefish, weakfish, fluke, black sea bass, tautog, dogfish, spotfish, blowfish, oyster toadfish, needlefish, sea robins, eels, and mummichogs.

⭐ Concerns About the Current Bay Cap

The current Bay Cap of 51,000 mt is no longer aligned with the coastwide TAC. As the Addendum notes:
"The 20% reduction applied to the TAC in 2026… increased the percentage of possible reduction fishery quota taken in the Chesapeake Bay from 32% to 40%."

⭐ Recommendations

---

1. A meaningful reduction in the Bay Cap (Section 3.1 – C1e and C2a)
2. Implementation of quota periods (Section 3.2 – B2)
3. Mandatory payback for overages (Section 3.2 – B)
4. Required review every three years (Section 3.3 – B)

Additional Recommendation:
If forage availability continues to decline, or if reductions to the Bay Cap do not stabilize predator impacts within the next review cycle, the Board should consider a temporary commercial pause (1–2 years) as a contingency measure. This would allow the ecosystem to recover while ongoing research improves understanding of menhaden availability, predator needs, and seasonal harvest dynamics.

⭐ Closing

Menhaden are not simply a commercial commodity. They are the foundation of the Chesapeake Bay food web. When their availability collapses, everything above them suffers — from small commercial fishermen to iconic species like striped bass and osprey.

Menhaden decline is not inevitable. It's preventable — but only if we act now.

Draft Addendum II is a critical opportunity to correct the course. I urge the Board to adopt the strongest possible measures to protect menhaden availability within the Bay and ensure a sustainable future for all user groups.

Respectfully submitted,
Linda Ann Higgins

Subject: Public Comment on Draft Addendum II to Amendment 3 to the Atlantic Menhaden Fishery Management Plan: Modifying the Chesapeake Bay Reduction Fishery Cap

To: Atlantic States Marine Fisheries Commission

I am writing to express my strong support for significant, precautionary reductions to the Chesapeake Bay reduction fishery cap under Draft Addendum II that consists of the recommendations of the Chesapeake Bay Foundation.

Atlantic menhaden play a foundational role in the Chesapeake Bay ecosystem, serving as a primary food source for striped bass, osprey, marine mammals, and other sportfish and wildlife. Given the ecological importance of menhaden within the Bay's nursery grounds, industrial reduction fishing in these confined waters poses a distinct risk of localized depletion.

To protect the Bay's food web, I strongly urge the Commission to adopt the following measures in Draft Addendum II:

Maximum Cap Reduction: Select the option that achieves the highest possible reduction—up to 50%—from the current cap of 51,000 metric tons. Reducing the cap to the maximum extent permitted under this addendum provides essential interim protection against localized depletion.

Seasonal Quota Distributions: Implement seasonal management limits to prevent industrial harvest from being concentrated during key months when resident predators, particularly breeding osprey and migrating striped bass, rely most heavily on menhaden as forage.

Precautionary Approach & Science-Based Limits: Continue moving toward full ecological reference points (ERPs) specific to the Chesapeake Bay, maintaining a precautionary stance or moratorium on industrial reduction fishing inside the Bay until localized depletion studies confirm that harvesting does not compromise ecosystem health.

The health of the Chesapeake Bay food web depends on maintaining robust menhaden populations in estuarine waters. I ask the Commission to prioritize ecosystem health and adopt the strongest conservation options presented in Draft Addendum II.

I have witnessed personally the impact of overfishing of menhaden on the Osprey population. I have participated in the Osprey Watch documenting sightings of ospreys at nesting stands, sightings of mating and nesting ospreys and seen firsthand the limited populations and infrequent nesting and mating and offspring around the Maryland central bay.

Thank you for the opportunity to comment.

Please work to limit the permissible annual commercial menhaden limit. It's always perplexing to me when people work against their own best interest. Would you rather catch all of a species make some $$$ and collapse the fishery, (cod in the North Atlantic) or show constraint to maintain a sustainable fishery to ensure a long career for yourself and those that follow? If the products that use the reduced menhaden increase in price due to more stringent catch limits then that higher price is a more accurate representation of the commodity's "true" cost. These fish are one of the foundational species for the bay. Their health and availability determines the general overall health of the bay. My voice will surely be faint compared to the larger commercial concerns, but I bet there are many that share my sentiment who simply don't, or don't know how, to express their concerns. I imagine that the commercial folks show up at meetings and conferences to make themselves heard. But just because they have a bigger megaphone doesn't mean they speak for everyone.

Re: Atlantic Menhaden Draft Addendum II

Dear Mr. Boyle and Members of the Atlantic Menhaden Management Board:

As the Alderman for Ward One in Annapolis, I write in support of Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden. While I am only speaking for myself in this letter, I have introduced a resolution—cosponsored by the Mayor and the Chair of the Environmental Matters Committee--expressing the entire city's support for Draft Addendum II, which I expect will pass before the board makes its decision.

Menhaden sit at the base of the Bay's food web. They are dense in calories and nutrients, and they make up a large share of the diet of striped bass, bluefish, dolphins, and osprey. When menhaden decline, the species that eat them will follow. In the Severn River, which borders Annapolis, I'm told that the 100 nesting pairs of ospreys only had 6 chicks survive during the most recent season. Many of the rest starved to death.

Annapolis depends on a productive Bay. Our charter captains, recreational anglers, watermen, marinas, and waterfront restaurants are a large part of our economy, and the Bay is central to the city's history and identity. Strong conservation of this little oily fish is an investment in all of it.

By reducing the Bay Cap by 50 percent, splitting it into three even-length quota, and requiring the Board to revisit the Bay Cap every three years, we can proactively protect our Bay while additional research is conducted. I ask the Board to adopt these measures at its November meeting.

Sincerely,

Harry M Huntley
Ward One Alderman
Annapolis, MD City Council

Dear Mr. Boyle,

Please do not approve an increase in the fishing of nearby atlantic shores. The egrets are suffering from small catches. They are not able to feed their young. The population has dropped severly this year.

I appreciate your help.

Sincerely,

Jo Ann Davidson

OCTOBER 1, 2026

Dear Mr. Boyle —

As members of The Chesapeake Bay Foundation and 20+ years subscribers and supporters of The Chesapeake Bay Journal, my husband and I have gotten a good education over the years regarding the menhaden/Omega Protein controversy.

We are very frustrated that after all the years of research and continued studies at taxpayer expense nothing has been done with the scientific data. Meanwhile, the can gets kicked down the road while menhaden stocks decline and the osprey population crashes. We are also sponsors of Tri-State Bird Rescue & Research in Newark, DE and they have been admitting more starving and sick osprey over the past 2 yrs. Since menhaden is a primary food source for them can we make a deduction? If starving and dead chicks (est. 5500) can't move the commission in the right direction, we hope alot of pissed off people will !!

We do get a real kick out of how Omega Protein portrays itself as a real "Mom and Pop" operation out of Reedville, Va. Thanks to the Internet a deep dive into Omega Protein reveals what it really is: A Canadian Mega-operation running a global industrial fishing fleet. And this is what we're suppose to be

helping? And 260 jobs in jeopardy in Reedville, Va? How many jobs are created along the Atlantic coast and the Chesapeake from healthy menhaden fish populations? And then — how many jobs will be lost as menhaden fish populations continue to decline?

Omega Protein has consistently violated our environmental laws and regulations. They are fined nothing compared to the damages done and the ecological impacts from menhaden dumps and over-fishing. Omega Protein seems to have an inordinate amount of influence over committees and the outcomes of countless taxpayer funded studies which never seem to have a conclusion based on the science of those studies.

We definitely want at least a 50% reduction on the allowed take of menhaden. AND that take needs to be spread over the season to minimize the impacts on the Osprey nesting and fledging season. This should also be applied to other species reproduction periods in the Bay. Years of research will back this reduction need up.

Finally, instead of always waiting for species to crash why doesn't the ASMFC try to play Offense instead of Defense with the menhaden and other critical Bay species?

Thank you —

Julie Slichter

Subject: [External] Menhaden cap

Stop letting corporations destroy the ecosystems that our local livelihood relies on!

We see the ships out there, stealing everything that belongs to us and our waterways! This feeds the local animals and keeps the whole system healthy and functioning. It also feeds all of us, indirectly or directly, through food on our tables or paychecks and cash flow.

Look at all the dead Osprey chicks starving! Parents cant explain to their kids why the nests they see each year are becoming empty. Our wildlife is starving. It is our responsibility to protect the whole of our system from people that want to scrape its entire value to send elsewhere.

Look out your window and tell me if you want to save life or be responsible for death and suffering

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I strongly support reducing the Chesapeake Bay reduction-fishery cap on menhaden and establishing strict seasonal quotas to lessen the effect of fishing over a longer period. Menhaden are critical to the Chesapeake Bay and the decline in the number of menhaden that the ospreys, striped bass and other marine life depend upon for their survival has been dramatic. Menhaden are at the lower end of the food chain and their numbers must be protected to save the ecosystem that they support.

For that reason, I urge the Commission to take the following actions:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.
2. Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.
3. Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.
4. Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just one Virginia based fishing company.

Thank you for your consideration.

Sincerely,

Brian Kulczycki
Valley Lee, St. Mary's County, Maryland

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I live in St. Mary's County and have watched the number of nesting pairs dwindle. Now it is a rarity to see chicks that fledge as they almost all die beforehand.

I strongly support reducing the Chesapeake Bay reduction-fishery cap by **50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

The evidence points to a decline in the number of menhaden that the ospreys, striped bass and other marine life in the Chesapeake watershed depend upon for their survival.

It is both when and where those fish are removed that matter. A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource.

The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. **One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users.**

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just one Virginia based fishing company.

We should not wait for further deterioration before taking action. There is no time for additional five-year studies to delay the decision. The severe drop in nesting pairs and the lack of surviving chicks will not replenish the species enough to survive that long.

As someone who lives and sails on the Potomac and the Chesapeake, I believe the Commission has an obligation to manage menhaden conservatively and to preserve health of the Bay.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.

Thank you,

Henrietta S. Kundert
Tall Timbers, St. Mary's County, Maryland

Subject: [External] Comments on proposed AddendumII

Tina Could you please enter these comments on Addendum II for the menhaden board And if possible let me know if the attachments can be printed out OK and if you receive this.
Thanks Tom L.

To James Boyle, Joe Cimino and the menhaden board members.

We wish we could enthusiastically support proposed Addendum II. We could if this Addendum followed the recommendations of your own protective options study group and its osprey subgroup that the season had to be closed in May and June.., See page 10 attachment one, . But, very unfortunately for our Chesapeake bay baby ospreys, this proposal drops the ball because it does not include the May-June closure that is absolutely necessary to prevent the baby Ospreys from starving again this spring. Unless you act to prevent this is this will your responsibility. You and only you can fix this.

This board has been researching the ways and means to take protective action to safeguard menhaden forage during the critical life stages of Bay wildlife for the last two years. You Concentrated

on the Osprey collapse. But, when the time came to do something with this Addendum the recommended option for a seasonal closure was left out. As a student in law school many years ago we were taught to look at legislative history of rule making to determine what the agency intended to do.... when we look at this we see that for the last two years the board has focused on the Osprey starvation problem , because in the words of the protective option group (attachment 2.) ospreys are a proxy for all the other Bay wildlife that rely on menhaden Forage, including striped bass. But, as we have said. when the time came for this addendum the specific seasonal closure for to June was not made an option. The Protective Options group studied And made recommendations based on ospreys because they are the most visible proxy for the condition of other Bay wildlife including stiped bass. See what was said at pg 1-2 0f their report to this board more that two years ago. Attachment 2.

There at least two options that you have if you want to protect Chesapeake Bay osprey babies from starvation this spring with this Addendum.

(1.) The enabling language from the board on this addendum allows you to pass rules to help the Bay ecology. So if you choose to do that you can put a zero cap for Virginia waters for the reduction fishery for May and June.

(2.) the second option is to amend the existing Addendum after the public hearings to add the May June closure. I believe the striped bass board made substantive changes and additions after the public hearings in their last addendum process so I believe there is precedent for you to do this if you care to.

I strongly believe that it is your responsibility with this Addendum to carry out the intent of the board to protect menhaden forage during the critical time of Chesapeake Bay wildlife and osprey babies in particular. That is the May June time According to your own protective options group and the Osprey scientists in the Osprey subgoup formed by your action. Will you consider that? Thank you for your consideration Thomas Lilly Whitehaven MD

MEMORANDUM

TO: Atlantic Menhaden Management Board

FROM: Atlantic Menhaden Work Group

DATE: April 23, 2025

SUBJECT: Precautionary Management of Chesapeake Bay

Executive Summary

At its August 2024 meeting, the Atlantic Menhaden Management Board (Board) agreed to form a Work Group of Board members to "consider and evaluate options for further precautionary management of Chesapeake Bay menhaden fisheries, including time and area closures to be protective of piscivorous birds and fish during critical points of their life cycle." This charge asserts there is an inadequate supply of menhaden to support overall predatory demand in the Bay. However, the Work Group addressed this charge without determining if there is or is not an adequate supply of menhaden to support predatory demand in the Bay. Instead, it has developed feasible management approaches, and it is the responsibility of the Board to determine if or when it is necessary to implement them. The Work Group represented a balance of different backgrounds, regions, and perspectives; the members were:

Martin Gary (NY, Chair), Ray Kane (MA), Rob LaFrance (CT), Loren Lustig (PA), Joe Cimino (NJ), Allison Colden (MD), Pat Geer (VA), Spud Woodward (GA).

The Work Group met nine times between September 2024 and April 2025 via webinar and in-person to discuss alternatives for precautionary management in Chesapeake Bay that could be considered if the Board chooses to initiate a management document. Additionally, the Work Group created two subgroups, which each met once in September 2024, to begin evaluating data sources for piscivorous bird and fish species, respectively. In addressing the Board task, the Work Group developed the following questions to guide their consideration of potential management approaches:

1. What is the problem any management action would address?
2. What are the priority species to consider, and what are the critical points of their life cycle?
3. What data can be used to support this discussion?
4. For each management strategy discussed, what are the benefits and implications?
5. How would the performance of potential measures be evaluated?

The availability of menhaden may be affected by changes in total abundance, size distribution of the population, and timing of presence and spatial distribution in the Bay, which can be caused by fishing pressure, environmental conditions, habitat suitability, and/or changing predation pressures on a limited spatial and temporal scale. Such changes in menhaden availability may affect the species' ability to fulfill its ecological and/or economic functions. Recent observations of below average commercial fisheries landings and declining population reproductive rates of ospreys within the mainstem Chesapeake Bay suggest that availability of menhaden in Chesapeake Bay is likely changing due to one or more of the above drivers.

Potential Management Approaches

Based on the life history of the predators examined, the nature of Chesapeake Bay menhaden fisheries, and recent changes in menhaden availability, the Work Group discussed a number of precautionary management options that the Board could consider for further action. The approaches listed below could be implemented individually or in combination, depending on the Board's risk tolerance and management goals. A full description of the background information considered and the potential management options under each approach can be found in the Work Group report.

A. Seasonal Closures

Many of the species examined are seasonal inhabitants of Chesapeake Bay, utilizing the area as spawning and nursery grounds. Some species, like striped bass, have population contingents that are full-time residents in the Bay while other individuals leave the Bay to join the coastal migratory stock. Bird predators, particularly osprey, show high consistency in their arrival and departure times in the Chesapeake Bay, with only slight variations from year to year due to weather patterns.

Due to the seasonality of predator demand in the Bay, seasonal closures may be a management option that could reduce menhaden harvest during certain times of the year that are critical to predators' life cycles. This option presumes that decreasing menhaden harvest during these times of year will allow more menhaden to be available as forage for predators. Although, the Work Group noted concerns that implementing seasonal closures may lead to a concentration of harvest effort during other times of the year with unknown or unintended consequences. The Work Group discussed a suite of possible seasonal closure options, which focus primarily on the needs of the osprey population as a proxy for other predators as they exhibit relatively predictable seasonal habits and are showing signs of food stress. Ospreys have the highest and most critical bioenergetic requirements between May 1st and August 15th, and the range of options discussed includes subsets of this timeframe with considerations for the impacts to ospreys and menhaden fisheries.

March 20, 2025

Response to Questions on Chesapeake Bay Osprey (*Pandion haliaetus*) Foraging Needs

Workgroup Members
Bryan Watts, Center for Conservation Biology, William & Mary, Williamsburg, VA

Allison Colden, Maryland Executive Director, Chesapeake Bay Foundation, Annapolis, MD
Barnett Rattner, U.S. Geological Survey, Eastern Ecological Science Center, Laurel, MD

What is the general timeframe of residence of ospreys in Chesapeake Bay?

Residency is generally 1 March through 15 September.

When do they typically arrive and when do they typically leave? How variable are those timelines?

Ospreys begin to arrive in the lower Bay in late February and arrival peaks by mid-March, and slightly later in the more northerly portions of the Bay (Bent 1937; Reese 1991; Watts and Paxton 2007). Most breeders are here by late March. A cutoff for arrival of breeders is typically taken to be 15 April. A second wave of birds arrives in the Bay in late May. These are subadults that are prospecting for territories that will be used the following year. These birds pair up and will often build a partial nest but do not lay eggs (referred to as house sitters; Poole 1989). Since these house sitters have not recruited into the breeding population, these pairs are not considered in estimates of population size or in calculating demographic rates.

Departure schedules for breeding adults and hatch-year birds differ by as much as a month with adults initiating migration in late August through mid-September and hatch-year birds leaving later (Poole 1989; Watts and Paxton 2007). It should be noted that during the early fall there is a mix of resident birds and migrants (from northern breeding populations beyond the Bay).

Arrival and departure are consistent year to year with some adjustments for weather, and the schedule could shift with climate change over time. It is likely that arrival time in the Bay advances with age of bird up to some stable point. Many resident birdwatchers who observe pair arrival report that birds have arrived at "their" nest often on the same date for years.

What is the general sequence of events during residency and when do they typically occur?

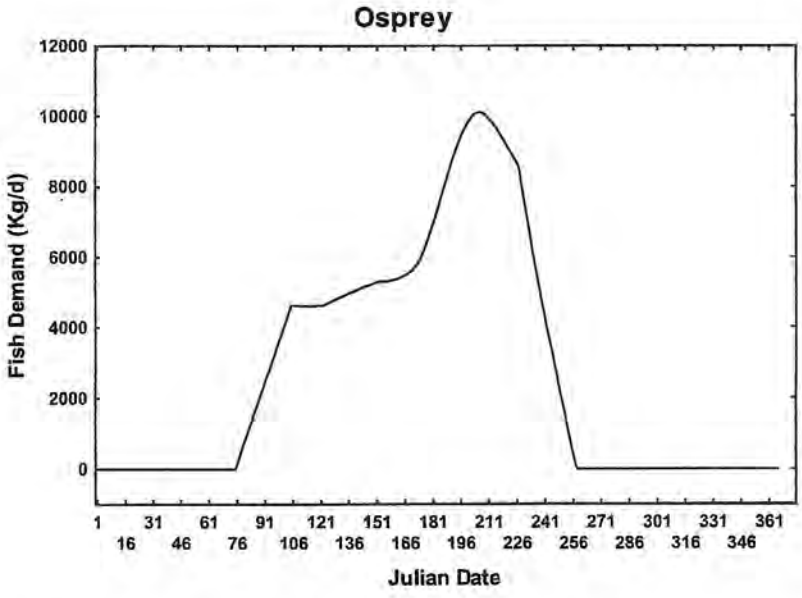
Adult Arrival – Late February through mid-April.
Nest Building – Peak 15 March – 15 April, but nest work can occur anytime.
Female Preparation for Laying – 1 to 31 March – effort includes female provisioning by male.

1 3/20/25

Laying – Early April through early May – Late layers are less successful; 2024 had both a high percentage of non-nesting adults and late clutches, observations that have not been previously documented.
Incubation – 39-day incubation period, both adults share duties, but female does more.
Hatching – Peaks during the second half of May.
Brood Rearing – First 3 weeks is the most critical period, male does most of the hunting, female does most of the brooding and care of young (referred to as nestlings or chicks), with the brooding period lasting 7-8 weeks.
Fledging – Most young (around 55-60 days old) in the Bay fledge in July (fledglings are young that are learning to hunt), and in 2024 some broods fledged later.
Post-fledging Period – Period between fledging and migration is a very vulnerable time for offspring. During the early part of the period, young are dependent on adults for food but less so over time as they learn to forage on their own.

Are there certain aspects of osprey life history during their residency in Chesapeake Bay that are more bioenergetically demanding than others? When do those activities occur? Are there estimates of consumption rates/needs?

The most bioenergetically demanding period during the annual cycle is when osprey pairs are raising broods. Historically, this period has been from mid-May through mid-July. In terms of population-level metabolic demand, estimates of the seasonality from years ago appear in the graph below (B.D. Watts, The Center for Conservation Biology, William and Mary, written communication, December 4, 2024). This graph was for a population size that is basically equivalent to that in the main stem of the Bay - the menhaden (*Brevoortia tyrannus*)-dependent area. Overall demand was estimated to be only about 1.2 million kg/year (seasonal peak is only around 10,000 kg/d). This indicates that the period of highest energy demand at the population level is from mid-May through mid-August. It is important to note that the period of peak demand is not necessarily the period of critical demand. Most broods are lost within the first 2 weeks of development. Their demand is relatively low at that age, but the adults must meet that demand, or they will die. Older chicks have more energetic reserves and can overcome short periods of food deficit. Young chicks cannot. It is critical that enough fish be available that can be captured by adults and delivered to the nest during the May period so that broods can make it through this bottleneck.



How does forage availability relate to consumption rate (how much biomass is needed relative to consumption to account for encounter rate, handling time, etc.?)

This is really the central question that remains to be resolved to understand the relationship between the stability of the osprey/consumer population and management of the fish stock. We know from various piscivorous bird studies around the world that reductions in fish stock can lead to reductions in avian provisioning rates that result in brood reduction and low reproductive rates (e.g., osprey: Poole 1982; Hagan 1986; Eriksson 1986; Bowman et al. 1989; Steidl and Griffin 1991; Machmer and Ydenberg 1998). Observations of declines in provisioning rates in parts of the Bay have resulted in reproductive rates below maintenance. Osprey very likely have a Type II functional response curve (i.e., consumption rate rises with prey density, but gradually decelerates until a plateau is reached at which consumption rate remains constant irrespective of prey density), such that a rapid increase in foraging rate with increasing prey density leads-to a population asymptote (B.D. Watts, The Center for Conservation Biology, William and Mary, written communication, December 4, 2024). If we could understand where along that curve osprey need to be to break even demographically, we could then solve for what density of fish they require. An independent assessment of fish abundance for a few osprey pairs (n = 15-20) could enhance our understanding of this relationship. Currently, such fish abundance data are not available to describe this relationship. One approach may be to develop a catch-per-unit effort foraging model and solve for relative fish abundance. This approach could support a better understanding of spatial and temporal variation in menhaden availability and its relationship to reproductive rates.

How do osprey typically identify and select nest sites?

Little is known about the nest selection process itself, but quite a bit is known about patterns of substrate use. Ospreys prefer to nest over water when appropriate substrates are available,

presumably related to the "escape from ground predator" benefits (Poole 1989). Use of duck blinds has been studied throughout the Bay and the probability of occupancy increases dramatically around >25-m offshore Watts and Paxton 2007). Prior to the 1960s, the majority of nests were on snags and live trees. Since the 1960s, the majority of nests have shifted to human-made structures (Watts et al. 2004; Watts and Paxton 2007). There have been a couple of waves of the appearance of human-made structures including the rapid expansion of aids to navigation during the 1970s, and then later the rapid expansion of private osprey platforms since the 1990s. Thus, there have been shifts in substrate use over time, but the general requirements remain unchanged. Ospreys prefer stable structures that offer protection from predators and are near adequate sources of fish (Poole 1989; Watts and Paxton 2007).

Are they well-established over time or do they move annually?

Ospreys exhibit high nest site fidelity. Generally, once a nest site has been established, the pair will use it for many years or until there has been a change to the structure (Poole 1989). If the nest is lost to weather or to human removal, the pair will rebuild the nest. However, if the structure itself is lost or altered in some functional way, the pair is forced to select another structure typically within a short distance of the original nest. Loss of nest substrate happens regularly due to various forces, such as ice flows eliminating duck blinds in particular years or more systematically as in the recent removal of many aids to navigation throughout the Bay by the U.S. Coast Guard (Watts and Paxton 2007). If no appropriate structure is available after its loss, the pair will move and find a new place. Nest substrate can certainly be limiting in various parts of the Bay, but more so historically than now due to the proliferation of nestable human-made structures.

What is the typical foraging range for osprey?

The distance that adult osprey forage from the nest varies from site to site. In some populations most of the foraging is within site of the nest (< 2 km), but in others it can range much further (15-20 km). Some individuals have preferred hunting areas and spend quite a bit of their time in those areas, while others are much more variable in where they forage. Across pairs, a high proportion of prey come from within 10 km of the nest site (Poole 1989).

What is the behavioral response if sufficient forage is not found within the typical range – looking farther afield, prey switching, something else?

Ospreys are adaptable foragers and certainly will adjust their hunting strategy as conditions change. This includes switching to less preferred prey, spending more time foraging, foraging farther away from nests, changing hunting tactics, etc. However, like all predators, ospreys have to maintain a positive energy balance. If they must travel too far or spend too much time to obtain the forage they need, then costs may exceed returns and their location is not viable. The limit to viability during the brood rearing period requires that adults meet the energetic demands of the brood. If they cannot, then the nest will fail. Recent diet simulation research suggests about 60% of the diet must be in the high-lipid category (including menhaden, eel, mackerel, etc.) to break even (B.D. Watts, The Center for Conservation Biology, William and Mary, written communication, December 4, 2024). This is not the case in some parts of the Bay. Prey

switching is not a panacea. Diet quality in terms of energy density has declined by 50% since the 1980s due to increased use of low-lipid prey (e.g., striped bass, white perch) by osprey (McLean and Byrd 1991, Glass and Watts 2009, Academia 2022).

What are the individual and population level impacts of insufficient forage for ospreys?

If an individual is not able to obtain enough fish to meet its basal metabolic demands, it will either emigrate or die. This presumably is what drove the evolution of their migration and also why they live in proximity to bodies of water. In terms of reproductive rate and broods, osprey have like many birds evolved a behavioral mechanism to match the brood demand to the available food. Many pairs in the Bay hatch three chicks. If there is enough food to provision all of the chicks, then all will develop and grow synchronously and survive. If there is not enough food to sufficiently provision the three chicks, then a dominance hierarchy will form, and the most subordinate young will be fed last. If this chick does not get enough food, it will die. If the second chick does not get enough food, it will also succumb to starvation. This process is referred to as brood reduction – reducing the brood and associated metabolic demand to match food availability. If the dominant chick does not get enough food, the nest will fail. Brood reduction on a large scale is an indicator of food stress (Poole 1982; Hagan 1986; Eriksson 1986; Bowman et al. 1989; Steidl and Griffin 1991; Machmer and Ydenberg 1998).

At the population level, the principal driver is whether or not adult pairs are producing enough young to offset average adult mortality. If they are producing just enough on average, then the population is expected to be stable. If they are producing a surplus, then the population is either stable or increasing depending on the circumstance. If the population is in deficit, then it would be expected to decline unless it is receiving immigration from another population. Net dispersal is why population size alone does not always follow local reproductive success.

How are those impacts typically measured?

There are a number of metrics that have been quantified that may be related to food stress. Some of these are generic (e.g., reproductive rate, brood reduction) and do not isolate food stress from other causes and other metrics are too costly to implement at scale (e.g., provisioning rate, nestling growth rate).

Notably, osprey nests have been monitored throughout fairly large portions of the Bay since the 1960s (Reese 1968; Reese 1969; Reese 1970; Henny 1974; Reese, 1975; Reese 1977; Rattner et al. 2004; Watts et al. 2004; Lazurus 2015; and Lazarus 2016). Coverage has been less consistent since the 1990s, but over the past couple of years there has been greater effort to increase geographic coverage of osprey reproduction in the Bay. This information is used to generate a number of metrics that are used to gauge impacts, including nesting success rate, reproductive rate, chick loss rate (brood reduction), percent one-chick broods, etc. Efforts are planned to develop some metrics that are practical, can be implemented at scale and reflect food deficit stress.

How have those indicators changed in Chesapeake Bay over the past 10-20 years?

For at least Mobjack Bay, substantial declines in reproductive rates, overall provisioning rates, provisioning rates with menhaden, proportion of the diet comprised by menhaden and diet quality have been documented. An increase in male foraging time and brood reduction has also been observed. Importantly, reproductive rates have transitioned from surplus to deficit (Academia and Watts 2023; Watts et al. 2024).

In 2024, 12 study areas were monitored in the Bay including 10 within the main stem of the Bay (salinity >10 ppt) and 2 in the lower salinity reaches (<1 ppt). All of the 10 sites were in reproductive deficit, while the 2 lower salinity reference sites were in reproductive surplus. It is believed that ospreys nesting in much of the main stem of the Bay are menhaden dependent. Osprey in the low salinity sites do not depend on menhaden as prey (Glass and Watts 2009; Lazarus et al. 2016).

In 2025, we plan to work across four salinity zones to examine reproductive rates to see if the Bay-wide population is at risk due to the low reproductive rates in the main stem of the Chesapeake. The four salinity zones would include low salinity (0 to <5 ppt), low mesohaline (5 to <12 ppt), high mesohaline (12 to <18 ppt), and polyhaline (18 to 30 ppt).

Is there a comprehensive list of osprey nest sites in the Chesapeake (which are natural and which are artificial)?

The last systematic survey of the Chesapeake Bay osprey population was completed in 1996 (Watts et al. 2004). This survey has been converted to a digital coverage with all nests mapped and all substrate types indicated. We do not have an updated coverage for the entire Bay. We have nest locations and substrate types for select study areas throughout the Bay totaling approximately 1,000 nests. As described previously, ospreys reproducing in the Chesapeake Bay nest primarily on human-made structures. As of the 1990s, greater than 90 percent of Chesapeake Bay osprey nests were located on human-made structures (Watts et al. 2007). Osprey pairs are distributed throughout the entire tidal portion of the Bay and beyond, wherever appropriate conditions are available.

RESEARCH DIRECTIONS TO MORE FULLY CHARACTERIZE THE RELATION OF MENHADEN TO THE SUSTAINABILITY OF OSPREYS IN THE CHESAPEAKE

Establishing a menhaden monitoring program for the Chesapeake Bay

Currently, there is no effective and biologically robust monitoring scheme of menhaden within the Chesapeake Bay ecosystem. This lack of a fisheries-independent assessment prevents evaluation of the potential impact of harvest on menhaden, which is required to set appropriate harvest regulations with respect to the needs of osprey. The lack of monitoring data on the scale of natural consumer populations also prevents directly linking changes in consumer populations to menhaden stock. Designing a menhaden monitoring program could support detection of spatial variation in menhaden abundance and identification of trends over time.

Summarizing and evaluating long-term historic data for the osprey in the Chesapeake Bay

Osprey breeding performance has been monitored throughout a large portion of the Chesapeake Bay for more than 50 years, including tens of thousands of nests and reproductive observations. A few papers have been published that address a specific list of questions. Gathering and compiling the existing raw monitoring data will create a . dataset that could allow for the evaluation of spatial and temporal patterns in breeding performance over a long time period.

Examining the historic relationship between osprey demographics and menhaden stock along the Atlantic Coast

Dozens of osprey monitoring programs exist along the Atlantic coast. Many of these programs were initiated during the DDT era and have continued for decades. Other monitoring efforts have been initiated in recent years or decades. An ongoing project by the Center for Conservation Biology (B.D. Watts, William and Mary, written communication, August 20, 2023) is to merge range-wide osprey monitoring efforts into a single dataset that may be used to evaluate the demographic response of breeding osprey to menhaden fluctuations. We plan to 1) develop an overview of existing monitoring data using a metadata template, 2) invite researchers with datasets to join a coalition and submit nest by nest data in a standardized format, 3) archive datasets in a common repository, 4) merge all data into a single centralized dataset and 5) evaluate the response of osprey demographics to menhaden and other explanatory variables within the appropriate spatial scale.

Investigating the role of climate in menhaden abundance in the Chesapeake Bay and related consumer populations

There is mounting evidence that natural events such as the Atlantic Multi-decadal Oscillation (AMO) may be shifting the center of biomass of menhaden to the north and may also be changing the phenology of entry into the Chesapeake Bay (Ney et al. 2014; Midway et al. 2020). Changes in abundance and phenology of menhaden related to climate change effects may be directly linked to recent shifts in consumer populations like osprey. Understanding these changes is critical to understanding options for mitigation.

Developing a metric of food stress in osprey that may be used as a monitoring tool for ecosystem conditions

Compile both recent and historic monitoring data to screen a number of candidates for development of a metric that may be measured economically and at scale for use as an effective indicator of food stress in osprey.

Developing an osprey catch-per-unit-effort (CPUE) model for menhaden

One of the challenges in understanding the relationship between osprey brood provisioning, demography and menhaden stock is that we have no estimates of menhaden availability on the local scale. One potential work around for this void is to develop a CPUE model (prey capture/time spent hunting) for males provisioning broods. Development of a CPUE model for menhaden (and other fish species) would allow us to better define the state space where osprey may meet demographic requirements within the time available for hunting. A CPUE-

demographic framework could lead to a simple monitoring program based on male hunting that would inform whether or not stock levels are adequate to sustain a viable osprey population. The intent in building the CPUE model would be to develop a metric that would be practical to apply on a broad scale to indicate when/where menhaden abundance is adequate to sustain the osprey population.

During the 2023 breeding season, we completed a proof-of-concept for pairing high output, three-dimensional tracking of males with nest cameras (B.D. Watts, The Center for Conservation Biology, William and Mary, written communication, August 20, 2023). This pairing can allow for quantifying male time budgets, determining the time allocated to hunting, estimating the duration of hunting forays (both length and time), identification of hunting areas, determining captures/attempts ratios and the identification of fish captured. These metrics could allow for the assessment of species-specific provisioning rates and the development of species-specific CPUE models.

OTHER ISSUES OF CONCERN

Overlap between menhaden harvest sites and osprey breeding

One approach to evaluate the relationship between commercial harvest of menhaden and impacts to osprey reproduction could be to quantify overlap between menhaden net sets and osprey study areas (i.e., locations where we have recently quantified reproductive rates). This approach assumes that menhaden are spatially static such that the impact of harvest is restricted to the locality of capture. Most of the net sets are concentrated around the lower eastern shore where menhaden enter the Bay. In effect, menhaden are being intercepted as they migrate into the Bay. This activity impacts downstream consumers just as dams restrict the migration of fish up into tributaries and impact consumers above the dam. A more realistic assumption could be that there is high connectivity between localities throughout the Bay, such that actions in one place are likely to impact availability of menhaden to consumers elsewhere. If there is high connectivity throughout the Bay, then we would expect low correspondence between where fish are taken and impacts to other specific locations.

Density-dependence in osprey reproductive rates

The decline in osprey reproductive rate may be driven by the increase in osprey numbers such that the increased numbers are cropping down the menhaden stock - a density-dependent process that is likely playing out. As has been indicated elsewhere, osprey do not have the capacity to crop down menhaden. McLean and Byrd (1991) point out that osprey consumption represents a fraction of one percent of the commercial harvest. Even if we consider all of the bird consumers during the breeding season, the consumption is less than five percent of commercial harvest (B.D. Watts, The Center for Conservation Biology, William and Mary, written communication, January 28, 2025). This is consistent with an "upper-limit" estimate of double-crested cormorant consumption of menhaden along the coast of North Carolina (Watts et al. 2023). Osprey simply do not have the metabolic capacity to exert control of menhaden stock.

Although it is possible that behavioral interactions among nearby pairs of nesting ospreys could reduce time spent foraging and impair productivity, this has not been apparent in the

COMMENTS ON MANAGEMENT OPTIONS

Seasonal Closures

Osprey and other bird species that depend on menhaden within the Chesapeake Bay are most sensitive to food shortages in the May and June time period. Mitigation measures designed to protect osprey or other bird species could attempt to insure high menhaden availability during this seasonal window.

Spatial Restrictions in Harvest

The current distribution of harvest appears like an intercept fishery, where fish are being harvested just before or as they enter the Bay. This effectively places the entire Bay in a compromised downstream position. If spatial restrictions are imposed, they could be around the mouth of the Bay where menhaden gain entry.

Use Osprey as Formal Ecological Reference Point

Osprey are a sensitive indicator of menhaden abundance within the main stem of the Bay. They could be formally listed as an ecological reference point and included within ecosystem management strategies. Specific reference conditions could be formally developed for osprey.

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board,

I am writing in support of stronger protections for Atlantic menhaden through Draft Addendum II. I urge the Board to adopt the following measures:

- **Reduce the Chesapeake Bay Reduction Fishery Cap by the full 50%.**
- **Link the Bay Cap to the coastwide catch limit**, so any reduction in the coastwide limit automatically reduces the Bay Cap.
- **Distribute Bay harvest across quota periods** to prevent concentrated removals in spring and summer and help maintain forage availability throughout the season.
- **Reduce the coastwide catch limit by 40% for 2027 and beyond**, as part of a science-based approach to protecting menhaden and the predators that depend on them.

As a Massachusetts recreational fisherman, I care deeply about maintaining healthy forage populations along the Atlantic coast. I ask the Board to prioritize the long-term health of the ecosystem and the fisheries it supports.

Thank you for considering my comments.

Dear Mr. Boyle,

Each month, Longwood Public Library hosts a Teen Sustainability Club in which students in grades 7 through 12 explore environmental issues, often with guest speakers who discuss our local ecosystem and wildlife. In September, we had the pleasure of welcoming a representative from Group for the East End to learn all about ospreys! After learning about these magnificent fish hawks, including where they are often spotted in our Suffolk County community, teens felt enthusiastic about protecting not only our local ospreys, but also their primary source of food: the menhaden fish.

Enclosed are letters written by some of our teen attendees. Thank you for your consideration and for the opportunity for our youth to exercise civic engagement and environmental advocacy!

With thanks,

Shelby Broderick and Megan Karaptis

Dear, Mr. Boyle

I live on Long Island, and I'd like for you to listen to us. Ospreys, a bird who lives on LI, mainly eat Bunkers. But their diet is 99% fish. This is the reason we're asking you guys to please decrease fishing quotas, due to the fact that an increased quota causes fish populations to plummet, and in turn, puts Ospreys' primary food source in danger.

THANK YOU!

- Joshua Battaglia

Dear Mr. Boyle,

I [redacted] live on long Island and I think not only wildlife but osprey are important to the environment and [redacted] that Bunker fish should be preserved for [redacted] a grow in population. I also value Osprey and the population status and an ongoing issue is the amount of Bunker fish be fished. It would be very appreciated if there was a limit in Bunker fish fishing to help Osprey.

- Gavin

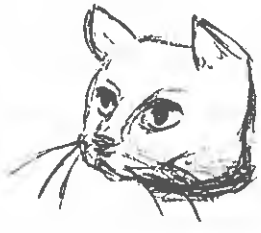
menhaden James Boyle James Bogle
a
bunker

bruh

Dear Mister Boyle

By reducing the percentage of how much menhaden / bunker fish, due to how this fish impacts the food chain & how it's a primary food source of the Osprey, the decline and reduction of these fish will impact the Osprey and any variety of other species that find these fish to be important to them in one way or another. Plus, those who enjoy birdwatching like to observe them, and if their primary food source were to be depleted- or worse- vanish- their population would, too.

Please consider decreasing the amount of Menhaden fish you allow fishers to take...



-Sincerly, Bella B.

Atlantic States Marine Fisheries Commission

re: Atlantic Menhaden Draft Addendum II

To Whom It May Concern,

I am writing to you to express my deep concern for the ultimate survival of the osprey population in the Maryland Chesapeake Bay region, which is being rapidly depleted due to the commercial over-fishing of their main source of nutrition… the menhaden fish population. This species of fish was previously naturally abundant in the Chesapeake Bay, but is now being commercially over-fished by a Canadian controlled fishing operation, with a direct impact on the survival rate of the osprey population. I beg you to please impose the proposed 50% reduction in the fishery cap (the "Bay Cap") of the Atlantic Menhaden Draft Addendum II.

My wife and I own a home on Mill Creek in Calvert County, Maryland. My parents actually purchased this waterfront property, and I enjoyed summers there as a small child more than 75 years ago. I grew up exploring the beautiful nature of the area year after year, and more recently, my wife and I rebuilt the original cottage into a retirement home. We have enjoyed and cherished this property for decades, as have our children, and our grandchildren.

We have enjoyed crabbing and fishing off of our dock, and we built a nesting platform for ospreys years ago. To our delight, the very first spring after we built the platform, a pair of osprey took the platform as their home, and have returned there year after year. Every year they produced two or three chicks and all members of our family have enjoyed watching the osprey parents hunt for fish, feed their young, and then watch those young chicks grow strong, test their wings, and then eventually fly off to form their own families in following years. The original osprey pair has returned each year to our nesting platform on Mill Creek in front of our property.

In the last three or four years, however, we have noted a decline in the production of chicks, and ultimately, the survival of the chicks produced. The last two years, no chicks have survived. We have heard similar tales from those in the area, and we have become desperately alarmed for the continuation of the osprey population in Maryland.

I recently attended a talk about this growing concern and came to learn of the essential need of the osprey for Omega-3 fatty acids for their strength and survival. Without this essential nutrient, they are simply not strong enough to seek fish for their food to the level required, nor are they able to obtain and

provide this rich, strengthening, food to their young chicks. The adult osprey become weakened, they either produce frail chicks who are, in turn, under nourished and die, or they produce no chicks at all.

The problem clearly leads back to the dramatic decline in the menhaden fish population. This fish contains the Omega-3 fatty acid at levels that no other species of fish even comes close to. The osprey eat fish…. only fish! When they ate previously abundant menhaden (with their high omega-3 fatty acids) the osprey survived. When they are forced to eat other fish (because of the absence of menhaden due to over-fishing of that specific fish), they perish.

This is not just my concern, or the concern of a handful individuals who have followed the osprey that nest near their property. The Center for Conservation Biology at William & Mary University confirmed that the 2026 osprey breeding season was the worst ever recorded in the Chesapeake Bay. Similar studies have noted a steady and dramatic decline in the osprey population over the last several years.

The primary culprit for this over-fishing of the menhaden population is a giant Canadian seafood corporation based in New Brunswick, Canada, known as Cooke, Inc. In 2017, Cooke, Inc. purchased an American company (Omega Protein), which operates a fleet known as Ocean Harvesters, out of Reedville, Virginia. This Canadian purchase of an American company was made to exploit Virginia fishing grounds, and siphon profits back to Canada.

Even setting aside the legal issues of possible violations of the American Fisheries Act, (which requires that commercial fishing vessels that operate in US waters be owned and controlled by American citizens), this company's purse-seine fishing boats literally vacuum up tens of thousands of metric tons of menhaden from the Virginia lower portions of the Chesapeake Bay every year. When fished to such extensive and complete levels at the mouth of the Chesapeake, little or no menhaden make their way up the Chesapeake to Maryland waters, as they used to naturally do.

Virginia is the only state on the east coast that still allows this industrial menhaden reduction inside its state waters.

To save the osprey from disappearing, we must allow their natural food source of menhaden to exist at sufficient levels. We are NOT asking for a ban on menhaden. We understand the commercial viability of their omega-3 fatty acids in a number of products. We are simply asking for an approval of the proposed "Bay Cap" under consideration by the Atlantic States Marine Fisheries Commission Draft Addendum II, which could lower the current 51 metric tons harvested to as low as 25,500 metric tons.

Thank you for your attention to this serious issue.

Sincerely,

Richard S. Mattison

To the Atlantic States Marine Fisheries Commission:

The health of Long Island Sound is directly tied to the Atlantic fisheries. This impacts local waterways like the Mystic River Watershed, Niantic River Watershed, Connecticut River Watershed, and all along the coast of Connecticut.

I volunteer with folks at the Alliance for the Mystic River Watershed who have directly observed what CT Audubon has already researched and discovered, that osprey populations are in decline because of starvation. Additional observations have been made of Great Blue Heron and Snowy Egret having to travel further inland to lakes for trout.

The Atlantic Marine Conservation Society and the Mystic Aquarium have noticed a sharp increase in the number of large mammals in Long Island Sound as well as an increase in woundings and deaths as they search for food following menhaden schools into the sound.

Osprey and other species that rely on menhaden do not have years longer to wait. Decisive action is needed now. **I am writing to request that the Commission reduce the fishery cap by fifty percent to ensure menhaden**, a foundation fish and key food source for Connecticut's ospreys, harbor seals, striped bass, otters, and whole ecosystems are not put into even greater danger.

Sincerely,

Dr. Meagan J.K. Moore

Re: Atlantic Menhaden Draft Addendum II

Dear Mr. Boyle,

Thank you for the opportunity to comment on the "Atlantic Menhaden Draft Addendum II". I am encouraged by the Atlantic Menhaden Management Board's (the Board) proposal to reduce fishing by 50 percent. Specifically, I align with the Chesapeake Bay Foundation's request to "reduce the Bay Cap by 50 percent in 2027 and implement quota periods to more effectively distribute reduction fishing pressure throughout the season". I urge the Board to finalize this proposal at its upcoming meeting later this Fall.

As a resident of Silver Spring, Maryland, I find myself in the Chesapeake Bay region not infrequently. My reason for encouraging the Board to adopt these measures is because I am an avid birder and am very concerned with what is happening to the Chesapeake Bay population of ospreys. As I am sure you and the Board are aware, recent reporting has shown a sharp decline in successful breeding pairs of osprey on the Chesapeake Bay, which has historically been the largest breeding population of osprey in the world.[i] Menhaden are crucial to the osprey's survival, and it is clear that a shortage of Menhaden is harming the osprey population.

I align with the Chesapeake Bay Foundation in advocating that the Board adopt the following within Addendum II:

> 3.1 Chesapeake Bay Reduction Fishery Cap Amount: Support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.
>
> 3.2 Chesapeake Bay Cap Distribution: Support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. Also, support option B which establishes quota period overage payback and rollover of unused quota within a fishing year.
>
> 3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

Osprey are one of the most cherished birds of our region and the Menhaden are critical to their survival. I love seeing the osprey over the bay and in surrounding areas, and to lose this

population would be heartbreaking. Please adopt these protective standards so our osprey can thrive.

Thank you again for the opportunity to comment.

Sincerely,

Paul Melmeyer
Resident of Silver Spring, Maryland

Subject: [External] Menhaden vs osprey population

This summer season we have had 2 osprey along our riverfront house on approximately 8-10 platforms they nest on vs 14+ last summer.

It is my understanding that osprey catch menhaden for food but that has diminished this summer due to the over fishing of menhaden by the entity located in Reedville, Va.
I read an article on this topic recently & I don't understand why the appropriate Va governmental entity continues to allow that level of fishing by this entity. Can some Va governmental entity not put some limits on them?

I believe that is possible & the proper thing to do as the osprey have disappeared as a result of not limiting that fishing activity which is an unfortunate & disappointing trend.

Thanks for reading.

By: .....

Dear Members of the Atlantic States Marine Fisheries Commission,

I am a full-time charter captain based out of Old Saybrook, Connecticut, at the mouth of the Connecticut River. I have been running charter fishing operations for 16 years and currently employ four other fishing guides. I am writing because I am seriously concerned about the future of my business and the future of the recreational fishing industry throughout the Northeast.

For more than 25 years, I have watched the Connecticut River and Long Island Sound support an enormous population of Atlantic menhaden. Historically, millions of bunker have entered the Connecticut River and surrounding waters every year. They are the foundation of our inshore ecosystem and, more importantly to my business, they are what drives our striped bass fishery.

Over the past three years, I have watched the menhaden population decline to the point where there is now **virtually no bunker left in the Connecticut River, Long Island Sound, or the adjacent rivers.**

The consequences are already being felt.

There are significantly fewer striped bass. We have virtually no bluefish. The lack of menhaden has directly correlated with the decline in the abundance of the predatory fish that depend on them. There simply isn't enough forage here to support the fishery we have historically had. **This is no longer a warning about what might happen. We are watching it happen right now.** The fishery is on the verge of collapsing, and I believe immediate action is necessary. We need to dramatically reduce the amount of menhaden being removed by the industrial reduction fishery and put the health of the ecosystem ahead of the interests of the reduction industry.

The economic consequences extend far beyond charter captains. Striped bass are the number-one target species for the majority of inshore recreational fishermen in the Northeast. The striped bass fishery supports charter captains and guides, but also tackle shops, marinas, boat dealers, fuel docks, restaurants, hotels, boat manufacturers, and countless other local businesses.

I employ four other guides. If this continues, **my business and hundreds of other charter operations and fishing guides throughout the Northeast are at risk.** The economic impact of a healthy recreational striped bass fishery reaches thousands of people and businesses.

We need to look at the scale of the economics here. We are allowing a relatively small industrial sector to remove enormous quantities of a forage species that supports an entire coastal ecosystem and a massive recreational fishing economy.

The Atlantic menhaden fishery needs to be managed for the health of the entire ecosystem—not simply for the benefit of the companies harvesting them.

I am urging the Atlantic States Marine Fisheries Commission to take immediate action to dramatically reduce industrial removal of menhaden and increase protection of this critical forage species.

Please listen to the people who are on the water every day. For those of us who make our living on these waters, the decline is impossible to ignore. We have watched the bunker disappear, and we are now watching the fishery that depends on them disappear with it.

We need to protect the bunker. We need to reduce the industrial harvest. And we need to do it now, before the recreational striped bass fishery and the businesses that depend on it are pushed beyond the point of recovery.

I would welcome the opportunity to speak with the Commission or its staff and provide firsthand observations and information from the Connecticut River and Long Island Sound. Thank you for your consideration.

Sincerely,

Captain Michael Roy

I support anything to reduce or eliminate the harvesting of menhaden in the Chesapeake Bay. Anytime I fish in the bay or mouth of the Rappahannock River after the menhaden fleet have been in the area, the fishing is reduced to nothing. The Bay is suffering from the lack of menhaden and the other fish they catch as a byproduct of netting the menhaden. Please do anything you can to save the Bay from the menhaden fishing fleet.

FORMAL COMMENTS ON ATLANTIC MENHADEN MANAGEMENT

Draft Addendum II and 2027–2029 Coastwide TAC Specifications

Submitted by Niels E. Moore | North Carolina | October 2026

To	Atlantic States Marine Fisheries Commission — Atlantic Menhaden Management Board
Position	Maintain the 51,000 mt Chesapeake Bay Cap; reject mandatory seasonal quota periods and automatic Bay Cap:TAC linkage; avoid further coastwide TAC reductions absent a demonstrated conservation need.
Deadline	October 9, 2026, 11:59 p.m. EST

Dear Chairman and Members of the Atlantic Menhaden Management Board:

I respectfully oppose further coastwide Atlantic menhaden TAC reductions that are not necessary to prevent overfishing, and I oppose additional Chesapeake Bay controls that would reduce the Bay Cap, automatically link it to the coastwide TAC, or divide it into mandatory seasonal quota periods. I support ecosystem-based management and scientifically defensible conservation. My concern is that precautionary objectives should not become de facto biological thresholds without a clear evidentiary basis.

I have worked professionally on Atlantic menhaden issues, including service as Director of the Menhaden Resource Council and participation in ASMFC Atlantic Menhaden Management Board matters. I offer these comments from the perspective of both conservation policy and practical fisheries management.

Executive Summary

- Atlantic menhaden are not overfished and overfishing is not occurring. ASMFC distinguishes the ERP F threshold, which determines overfishing status, from the lower F target, which functions as an additional buffer and management objective.[1]
- The 2026 TAC of 186,840 mt is already 20% below the prior TAC and was projected to have a 0% probability of exceeding the ERP F threshold in 2026; the 2025 projection table likewise shows 0% threshold exceedance for 2026–2028 at 186,840 mt.[2]
- Draft Addendum II itself recognizes significant uncertainty concerning Chesapeake Bay abundance, distribution, and the localized effects of fishing. The present 51,000 mt Bay Cap is already a precautionary measure, not a Bay-specific biological threshold.[3]
- Recent pound-net declines deserve investigation, but temporal co-occurrence with concentrated reduction harvest does not establish causation. Permanent spatial and seasonal

[1] ASMFC, Atlantic Menhaden species page (2026 stock status: not overfished; overfishing not occurring), https://asmfc.org/species/atlantic-menhaden/.

[2] ASMFC, 2025 Atlantic Menhaden Stock Assessment Update, Table 5 (ERP F threshold projections), October 2025.

[3] ASMFC, Draft Addendum II to Amendment 3 (August 2026), Chesapeake Bay Cap background and discussion of scientific uncertainty.

restrictions should follow—not precede—analysis capable of separating fishing effects from movement, recruitment, environment, predator abundance, and other factors.

1. Do Not Convert the ERP F Target Into a Second Threshold

The most important management distinction in this debate is the difference between the ERP F target and the ERP F threshold. A target is an appropriate objective toward which managers may seek to move the fishery; it is not synonymous with overfishing. ASMFC currently classifies the stock as not overfished and not experiencing overfishing.

That distinction has practical consequences. If every excursion above the target automatically requires successive TAC reductions until F reaches the target, the target effectively becomes a binding ceiling. Before taking that approach, the Board should identify the incremental ecological benefit expected from each additional reduction and weigh that benefit against the associated economic and operational costs.

ASMFC's 2025 projection table illustrates the point. At the former 233,550 mt TAC, projected probabilities of exceeding the ERP F threshold were only 1% in 2026 and 4% in 2027 and 2028. At the reduced 186,840 mt TAC, those probabilities are 0% in all three years, while F is still projected to remain above the ERP target. The Board therefore should not characterize additional reductions as necessary to "end overfishing." Overfishing is not occurring. The policy question is how aggressively to pursue a lower target when threshold risk is already extremely low.

2. Further Coastwide TAC Reductions Require a Demonstrated Incremental Benefit

The 2026 TAC represents a substantial reduction from 233,550 mt to 186,840 mt. ASMFC explained that this 20% reduction was selected even though a reduction of roughly 50% or more would have been needed to materially lower the probability of remaining above the ERP F target.[4] That decision appropriately recognized that reference-point optimization is not costless.

For the 2027–2029 specifications, the Board should require a specific showing of what additional conservation benefit would result from any further reduction below 186,840 mt. It is not enough to say that a lower TAC moves F closer to the target; virtually any reduction does that mathematically. The relevant question is whether the additional reduction materially improves ecosystem outcomes in a manner proportionate to its costs.

3. Chesapeake Bay Restrictions Rest on a Much Weaker Quantitative Foundation

The scientific foundation for Bay-specific limits is materially different from the foundation for the coastwide TAC. The coastwide TAC is informed by a coastwide stock assessment and ecosystem reference points. By contrast, Draft Addendum II acknowledges uncertainty in the ability to characterize menhaden abundance, distribution, and fishing effects within Chesapeake Bay at the spatial scale necessary to resolve localized-depletion concerns.

That uncertainty does not mean ASMFC lacks authority to act precautionarily. It does mean that a numerically precise Bay reduction—10%, 20%, 30%, or 50%—should not be presented as though a Bay-specific stock assessment has identified a corresponding biological requirement. The current 51,000 mt Bay Cap itself resulted from a precautionary management history and was

[4] ASMFC, "Atlantic Menhaden Board Reduces 2026 TAC by 20% and Initiates Addendum for Chesapeake Bay Cap," October 2025.

reduced in 2018 to approximately reflect recent average reduction landings, not because a Bay-scale F threshold had been calculated. [3]

Accordingly, the Commission should retain the existing cap unless the record demonstrates that a lower level is necessary to address a defined conservation problem. Layering new precaution upon an already precautionary cap should require more than the existence of uncertainty.

4. Correlation With Pound-Net Performance Does Not Establish Causation

Draft Addendum II was initiated in response to concerns that more concentrated reduction-fishery effort may be affecting other fisheries and producing other ecological effects in the Bay.[5] Those concerns warrant research and monitoring. They are not equivalent to proof that reduction harvest caused recent changes in pound-net landings or CPUE.

Menhaden availability within a particular portion of Chesapeake Bay can be affected by recruitment, movement, temperature, salinity, habitat, predator abundance, school size, weather, fishing effort, market conditions, and other factors. A management action that attributes pound-net declines principally to reduction harvest should therefore be supported by analysis capable of separating those effects. Where the current data cannot resolve the mechanism at the necessary spatial and temporal scale, the appropriate response is additional research rather than permanent controls built around an assumed causal relationship.

5. Reject Mandatory Seasonal Quota Periods

The proposed quota-period alternatives would prescribe how much of the annual Bay Cap may be taken during specified portions of the fishing season.[6] That approach imposes calendar precision on a highly mobile schooling species whose availability can vary substantially among years and within seasons.

If the annual Bay Cap remains unchanged, redistributing the same allowable annual removals among calendar periods does not necessarily reduce annual fishing mortality. It may instead prevent efficient harvest when fish are available and push vessels and processing operations into less efficient periods. Before adopting such restrictions, the Board should identify the ecological mechanism through which the timing controls are expected to produce a measurable conservation benefit, and the evidence supporting that mechanism.

6. Reject Automatic Bay Cap:TAC Linkage

Draft Addendum II also considers linking the Chesapeake Bay Cap to the coastwide TAC so that future coastwide TAC changes automatically produce corresponding Bay Cap changes.[7] That would create an appearance of scientific precision without demonstrating that Chesapeake Bay abundance, localized fishing pressure, or predator forage availability changes in the same proportion as the coastwide TAC.

---

[5] ASMFC, Atlantic Menhaden Draft Addendum II Action Tracker (2026).

[6] ASMFC, Draft Addendum II Action Tracker and Draft Addendum II (2026), management options for seasonal quota periods.

[7] ASMFC, Draft Addendum II Action Tracker and Draft Addendum II (2026), management options for Bay Cap linkage to the coastwide TAC.

The two controls address different spatial questions and rest on different analytical foundations. Until the relationship between coastwide stock conditions and Bay-specific abundance or ecological risk is quantified, the Board should evaluate the Bay Cap on its own evidentiary record rather than mechanically tying it to future TAC changes.

Requested Board Action

- Do not further reduce the coastwide TAC solely to move F toward the ERP target while F remains below the ERP threshold; require a demonstrated incremental conservation benefit for any additional reduction.
- Select Draft Addendum II Section 3.1, Option A (Status Quo), and maintain the Chesapeake Bay Reduction Fishery Cap at 51,000 mt.
- Select Section 3.2.1, Option A (Status Quo), and reject mandatory seasonal quota periods.
- Reject automatic linkage of the Bay Cap to the coastwide TAC.
- Prioritize Bay-specific research on abundance, movement, fishing pressure, predator demand, and localized depletion before imposing additional permanent spatial or temporal controls.

Sound fisheries management requires matching restrictions to demonstrated biological need. Here, the stock is not overfished, overfishing is not occurring, the current TAC already provides a very large modeled buffer against the ERP threshold, and the Commission recognizes substantial uncertainty concerning Chesapeake Bay-specific effects. The defensible course is to retain existing Bay controls, complete the necessary research, and require a clear conservation rationale before layering additional coastwide, spatial, and temporal restrictions on the fishery.

Thank you for considering these comments.

Respectfully yours,

/s/

Subject: [External] Public comment - cap on bunkers/menhaden

I just read a piece in the Sandpiper that rightly called out the concerning loss of baitfish like bunker/menhaden in East Coast waters, but particularly in New Jersey waters.

Not due to environmental changes or natural disasters, but a commercial fishing cap that is devastating the population. This is a critical species for survival of osprey and others. In a year when multiple duck species are seeing a fall-off in surviving offspring due to starvation.

We have seen the mistake of overfishing happen decade after decade elsewhere, with permanent losses that will never be recovered.

Residents of New Jersey want to PREVENT a tragedy from happening. The caps are set for a reason, and must serve their purpose.

The "aggressive" 50% reduction is the bare minimum. Our wildlife is a crown jewel of our state.

We are responsible for not destroying it any more than we already are - especially not to foreign multi-million-dollar companies.

RE: Draft Addendum II to Amendment 3 to the Interstate Fishery Management Plan for Atlantic Menhaden

My name is Terri O'Rourke, I am an Audubon Steward residing in a Connecticut coastal community. This past year has been catastrophic for the Osprey in Clinton due to starvation. I have created a brief presentation documenting both Clinton's Osprey nest failure rate as well as my neighborhoods. I strongly urge the Commission to enact quickly the most significant caps to reduction fishing of menhaden, and any other menhaden fishing that warrants it, both in the Bay and the Atlantic. Anything less may result in a complete failure for the Osprey. Most statistics refer to nest failures, but that doesn't capture the full picture of the die off. I know data about hatchlings and success at that level, rather than nest level, is limited, but it more accurately reflects the urgency of the situation. We are all simply devastated by what's happening, Please, enact significant caps to protect the supply of menhaden for the birds, sea life and other wildlife.
Respectfully, Terri O'Rourke, Audubon Steward, 7 Harbor Pkwy, Clinton CT 06413
Below is a link to the Google Presentation, as well as a pdf copy.

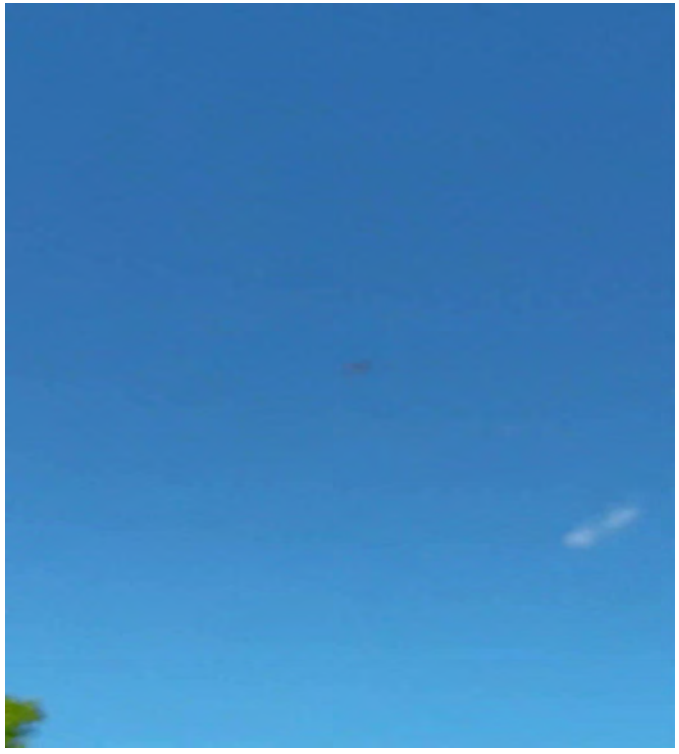
Clinton CT Osprey

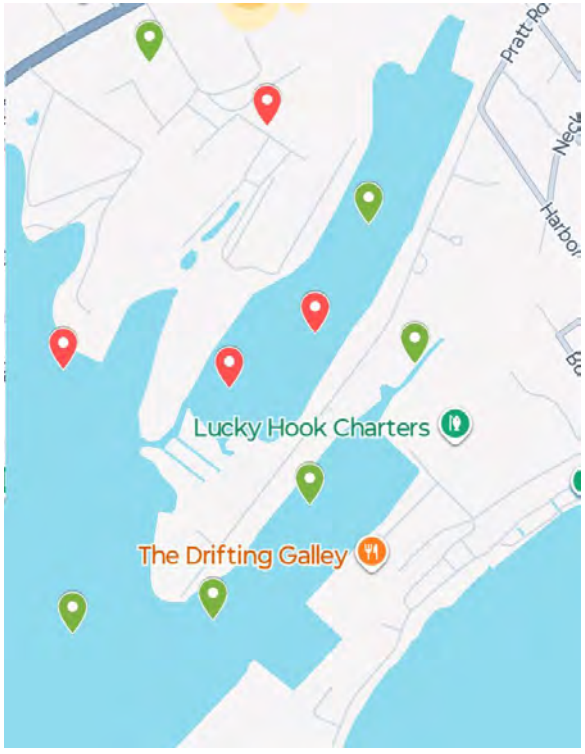
The Pratt Road Nests
Summer 2026

Terri ORourke
CT Audubon Steward
7 Harbor Pkwy, Clinton, CT 06413

One Neighborhood's Osprey

Pratt Road, Clinton Connecticut





Clinton Connecticut is home to 40 nesting sites. The Pratt Rd neighborhood has 8 of these nests in close proximity to residents homes. One of these has a live audubon camera.

The short video is what our skies typically sound like, May 2026

Clinton Nests

- Clinton has 40 nests. Observations indicated 28 were active this year. On those nests, 42 chicks were hatched. By July, only 7 chicks were observed.
- 7 chicks on 28 nests looks like 25% success.
- 7 chicks out of 42 hatchlings is really 16.7% success.

Pratt Road Nests

- There were 7 platform nests at the start of the season, 1 new tree nest was discovered mid season. 6 nests were observed as active, producing 15 hatchlings. By July, only 2 chicks were observed. 4 nests that are normally highly successful lost 13 chicks.

- 2 chicks on 6 nests looks like a 33.3% success rate.

- 2 chicks of 15 hatchlings is really a 13.3% success rate.

Nests normally highly successful, failed this year, most failed very early. Stewards in very close proximity to their nests were devastated watching parents struggle to catch fish, feed themselves and their chicks. Fish being caught appeared to be very small. Observers noted adult Osprey were out fishing for hours. Some Osprey parents gave up, abandoning their chicks.

Statistics tell one part of the story, but these birds are well loved. It is shocking to witness such a fast and catastrophic decline. It is especially upsetting when a camera feed bares witness to starvation, and the actions survival requires. What follows are some screen captures of loss and survival.

Camera Nest - 3 Chicks hatch by mid June.
June 26 Chick 1 dominates feeding time, denying 2 and 3 any food until it is gorged.

June 28 Dad brings fish back and consumes it completely.
All while Mom calls repeatedly.
She often leaves chicks unattended to fish.

June 30 As fewer and smaller fish are brought in, as Chick 1 and 2 grow, Chick 3 gets less and less.

July 3 - This Osprey Mom is experienced, and a very protective mother. Pictured providing some shade for the chicks, but few fish are brought to the nest.

July 3 – evening – Mom leaves to get fish. Chick 3 in foreground hasn't eaten at all that day. Note Chick 1 has a full crop.

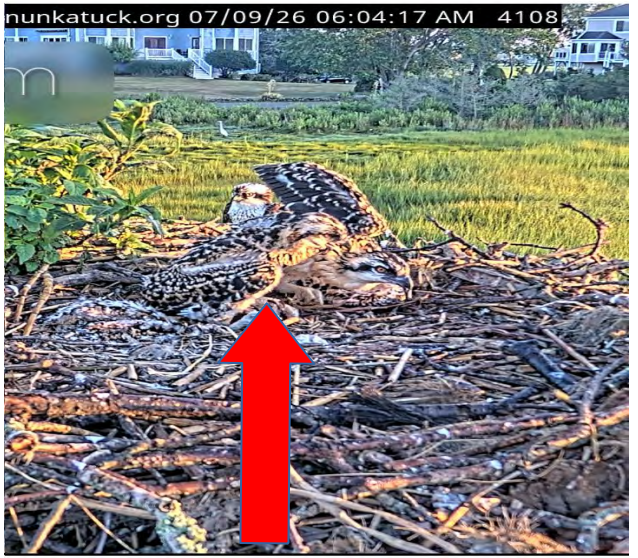
July 4 – evening – Chick 3 in foreground, got some food, pictured with a full crop, all three chicks were fed.

July 5 – Chicks 1 and 2 are preventing Chick 3 from receiving any food. Mom goes to find Dad at 5:45 pm to get him out for some fish. A feeding takes place at 7:45, but 3 goes the entire day without food and 2 gets very little.

July 6 – is a stormy day, with heavy rain. Mom uses her body and the plant to provide some protection to the chicks. Neither she nor the chicks eat at all during the day. Chick 3 dies during the storm. The other chicks are exhausted.

July 7 – sometime between 5 and 7 am, Mom leaves the nest. She does not return for more than 24 hours. The chicks did not eat July 6 and will not eat at all on July 7.

July 8 – around 9 am Mom returns and resumes feeding the chicks. Chick 1 is now blocking Chick 2 from getting much more than a few bites.



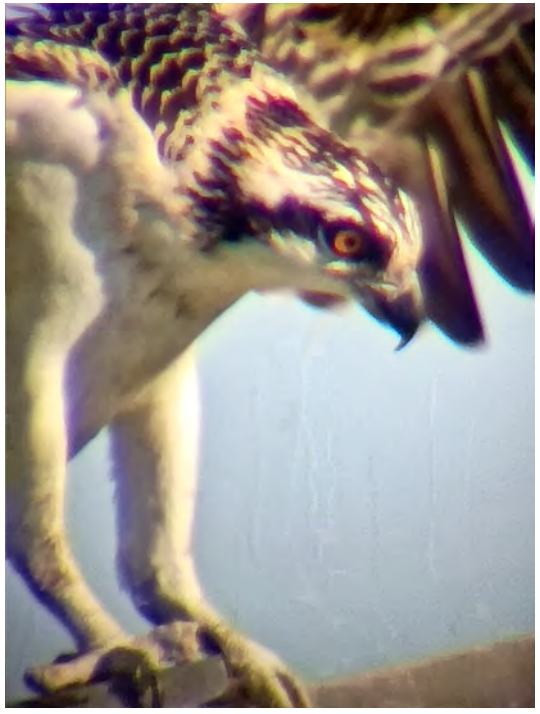
July 9 – Chick 2 is actively dying. It dies during the day, slowly on camera for all to see. It literally starves to death in front of us.

Of 15 hatchlings in this neighborhood there are now only 2 surviving.

In prior years, and in other nests with multiple chicks, the fight for food among chicks lessens as the supply of fish is consistently sufficient for the nest. In the camera nest, the behavior with Chick 1 battling the other 2 for food was very hard to watch and only intensified as the size of the fish and the volume of fish wasn't enough.

The adults spend the rest of July feeding the remaining chick, though some days are tough and some days are filled with multiple feedings.

The skies above the neighborhood are very quiet. Only when the two remaining neighborhood chicks near fledging do we hear a few ospreys enjoying the sky again.



August 4 Chick 1 fledges. And on its very short 2nd flight scares itself by flying into a flag and flagpole.

August 11 – 13
a visitor joins Chick 1, aka chickzilla, and stays a few days. They tussle and eventually the visitor leaves after getting some food from Dad.

Observations on social media from other stewards note the occurrence of visitors to other nests for several days is happening in multiple locations.

Sept 2– Chick 1 was still visiting the nest during the day calling for food. No observations noted as to whether the chick is catching fish on its own.

Dad has been encouraging the chick to fish, delaying food delivery for hours.

Chick acts ferocious and protective of the fish, but Dad delivered it!

While Clinton focuses on 7 surviving chicks, what will our population look like in two years. We had at least 56 adults in the area this summer, what will that look like next year if there is no food during their migrations?

It is clear there was a serious problem with menhaden for the shoreline osprey. Fishermen throughout the area reported the absence of menhaden/bunker fish for most of the summer.

It is urgent for the commission to do something now to reduce the volume of menhaden being removed from the food supply for the birds and other sea life.

The skies went silent this year; it's a human caused problem and it requires an immediate human solution.

Comments regarding specific Addendum:
3.1 Chesapeake Bay Reduction Fishery Cap Amount
Option C. Linking the Bay Cap to Coastwide TAC
C1e 13.6% 50% reduction to 2026 Bay Cap : 2026 TAC 25,500 mt
C2a. 51,000 mt Lower: None Upper: Current Bay Cap
Option B. Three Quota Periods
B2 Even Length & Uneven Harvest 9 weeks May 3–Jul 4 25% 10 weeks Jul 5–Sep 12 25% 9 weeks and 5 days Sep 13–Nov 19 50%
Option B. Quota period overage payback with rollover of unused quota within a fishing year.
Option B. Revisit Provision. The Chesapeake Bay Cap will be revisited every three years following implementation of this draft addendum. AT A MINIMUM

It was my intent to specify the most significant reductions proposed, both for Chesapeake Bay and the Atlantic.

Regarding the Harvest period, I know our birds migrate in September, leaving throughout the month. I want to ensure that harvesting in the 3rd period still protects the birds food supply.

Arlington, VA 22201

October 4, 2036

Dear Members of the Marine Fisheries Council,

I write to recommend significant reductions in the Atlantic Menhaden catch due to a significant risk in the stability of the fish stocks and the short and long term negative impacts on the environment.

As an economist, I will particularly focus on the economic analysis provided in the draft impact statement (Section 2.3: Social and Economic Impacts). In my view, it is quite deficient in terms of capturing the real economic impacts as well as the significant risks that are likely to occur based on an overfishing of this resource.

In detail, the economic analysis focuses on the potential negative impact of the harvest changes that may cause a reduction of 98 direct jobs in the fish meal & oil (reduction) industry in Virginia and yet has no analysis of the significant potential gains or preservation of value due to a reduced fish meal & oil harvest.

In reality, the fish meal & oil process harvests the vast bulk of the catch of menhaden in an industrial fashion that yields an effective catch that is 100% of the allowable harvest limits. Yet, undiscussed in the economic analysis is the potential risk of overfishing of the menhaden stocks and the potential loss of the other areas of economic value created and supported by the menhaden stock. This includes the commercial collection of menhaden for bait in support of the recreational fishing industry and recreational anglers. Also, the stock of menhaden supports and sustains the population of recreational game fish and commercial food fisheries. Further, the stock of menhaden provides the food stocks for many other species including birds, gamefish and other littoral species.

I also note that no value is provide for the benefit caused by the reduction in bycatch losses of other fish species if there was a reduction in the fish meal & oil catches. This would be a positive impact of significant value that is not valued in the Draft Addendum II (August 2026). Even given a very conservative value ($4.00 a pound) of the bycatch (3.6% of menhaden tonnage) and a small percentage (20%) of the bycatch that turns into food fish stocks – the economic value of these landings could be twice the value of each pound of menhaden.

CUNY

The economic value of tourism, recreational fishing, bird watching and nature visits should and must be included in the economic analysis of the impact of the menhaden catch reduction. The reduction in economic activity caused by the reduction in the fish meal & oil industry take of menhaden should be properly compared to the significant potential gain in value and reduction in risk to the economic activity and jobs that are potentially at risk due to the overfishing of the menhaden stocks.

No analysis of the risk of the higher catch limits and the resulting downstream impacts of the loss in recreation activities as well as the significant disruption in the natural environment are included in the report. This should be corrected and evaluated in the decision process.

Sensible economic analysis would speak to conservation of the fish stocks and implementing a harvest target that is highly likely to result in a stable and growing fish stock as the prudent course of action. If we have a significant overfishing of the stock that leads to a subsequent collapse of the fishery – we then face a recovery process with negative impacts that may last a decade or more. Underfishing has significantly more economic potential as compared to overfishing – as a strong fishery can be managed for long term value with improved future catch limits – as opposed to an overfished stock – where negative impacts spill over into other sectors and dramatic actions are then needed to rebuild stocks.

The recent Presidential Executive Order 14430 of September 17, 2026 appears to me to suggest a course of action for the management of the menhaden fishery focusing on preserving recreational fishing and the natural environment.

I would be happy to work with your staff on the quantification of these impacts as well as a full discussion of the risk quantification that should be performed to fully value the proper management of this important natural resource,

Please feel free to reach out to me if you want to discuss this further or have any questions.

Yours truly,

As a follow up to the conference I wanted to reiterate that ospreys are an indicator species. Their decline reflects the complete overfishing of Menhaden which are essential to their health and to the heath and survival of other marine life. We in Connecticut have worked hard to restore the osprey population not to see them starve. In Great Island only seven fledglings survived, out of over one hundred nests, an unsustainable and unheard of loss. The Chesapeake Bay needs to be protected as a nursery for Menhaden not to be subject to unsustainable fishing. Please put the most restrictive limits on Menhaden fishing to protect our ospreys and all the other life that depend on them.

Mr. Boyle,
As Fishery Management Plan Coordinator, I was writing just to let you know how critical our avian populations are right now. The decline of osprey in this area will have lasting impacts. I hope you guys are aggressive with the policy to manage overfishing. Thank you!

My name is Amy Glotfelty. I'm an Anne Arundel County resident and wildlife photographer. For the last 4 years, I've spent approximately ten hours a week observing osprey throughout their season, including two nests at Fort Smallwood Park in Pasadena, MD and from water access near my home nearby. My dedication to their ongoing conservation grows with each year I spend watching another season of osprey life unfold.

I have noticed a concerning trend of negative outcomes for the 2 nests I have observed, as have studies completed by The Center for Conservation Biology (CCB) (https://ccbbirds.org). Their tracking has revealed a severe, compounding, multi-year reproductive collapse along the high salinity mainstem of the Bay:

- 2024: .51 young per pair
- 2025: .35 young per pair
- 2026: .25 young per pair

2026 was officially documented as the worst productivity year ever recorded in Chesapeake Bay history due to widespread starvation.

Personal Observations

Over these 4 years of observation, I observed the following in these Fort Smallwood Nests:

	2026	2025	2024	2023
Nest #1	1	1	1	2
Nest #2	2	0	2	1
Total	3	1	3	3
Detail of chicks with uncertain outc	One juvenille from the 2nd nest fledged in early August, but then was not seen again after 8/11, subsequent survival unknown		The sole juvenille from nest 1 became entagled in fishing line (impacting one leg/talon), later survival unknown	
# of Likely Successful Chicks	2	1	0	3

The two nests showed substantial annual and nest-specific variation. However, the 2026 record contains repeated observations consistent with feeding difficulty. The most concerning behaviors were concentrated in late July and August 2026. Specific changes in behavior included the following:

- Juveniles calling for their parents for prolonged periods.
- Fewer deliveries of fish that I identified as menhaden and more deliveries of other fish species. On some days, I watched for approximately four hours without observing a single fish delivery. That does not establish that they went the entire day without food, but those extended periods were concerning.
- Adults appeared to travel further (bringing fish from open water instead of shoreline) and remain away longer during fishing trips. Repeated aborted dive attempts.
- Reduced adult perching at nest later in season.
- Sibling competition, and later aggression when fish was delivered. The stronger juvenile monopolized the fish, refusing to share with its sibling, resulting in the 2nd juvenile spending

noticeably more time sleeping and it appeared more lethargic than young birds I had observed in previous years.
- Juveniles did not begin to flap their wings or attempt to fledge until beginning to mid-August, compared with approximately mid-July in previous years

The most significant period of the above behavior developments was observed between July 24 through August 22.

- July 24, adults were rarely seen perching at either nest from this date forward, juveniles were begging frequently, and only one nest delivery had been observed during approximately seven hours of observation over the preceding week.
- July 26, juveniles at both nests were observed begging continuously during morning and evening observation periods. Sibling competition was observed at Nest 2, with one juvenile consuming most of the food and the other lying down between begging periods.
- August 1, adults were observed aborting some dives before entering the water. Two fish were nevertheless delivered to Nest 2 during that visit and significant sibling aggression was observed.
- August 11 – The stronger juvenile from nest 2 disappeared after fledging a few days earlier. It was no longer seen at the nest or nearby for the remainder of the time. It's subsequent fate is uncertain.
- August 22, the remaining observed Nest 2 juvenile caught a fish, ate only a few small pieces, abandoned it, and then begged from an adult

Together, these observations establish a coherent period of concerning feeding and juvenile behavior. I realize theses are repeated personal observations and not a controlled scientific study. They are specific to 2 nests and cannot necessarily be extrapolated to the full osprey population. However, my history with these nests gave me a clear baseline to evaluate the 2026 behavior changes against. I cannot establish that food shortages caused these behaviors or that menhaden harvest caused a shortage, but I believe these observations warrant attention and reinforce the need to monitor whether forage is available where and when osprey need it.

Additional Contextual Research/Data Analysis

Throughout the period of my 2026 observations, I gathered additional data to try to better understand what all the factors were that could be contributing to the changes I had observed. In addition to fish availability, I also wondered if changes in water quality, pollution, extreme heat or the frequency/severity of strong storms could also be contributing to the apparent reduction in forage ability and nesting outcomes. I pulled data for 2023-2026 as specific to the nests I was observing and have included what I found below for additional context.

<u>Fish Availability</u>

Bay-wide indices varied considerably by species from 2023 through 2025 rather than showing one uniform trend. Menhaden and spot indices were lower in 2025 than in 2023, while herring increased modestly and white perch increased substantially.

Species	2023	2024	2025	2023–2025 change	2025 vs. 2013–2022 median
Menhaden	3.782	3.659	2.536	-32.9%	96.9%
Spot	0.844	3.815	0.71	-15.9%	59.6%
Herring	0.088	0.019	0.129	46.1%	-7.0%
White Perch	0.981	1.227	5.125	422.5%	-17.6%

Source: Maryland DNR Juvenile Striped Bass Survey data (2026 not yet available) *for Bay and Head of Bay Locations. (https://dnr.maryland.gov/fisheries/Pages/striped-bass/juvenile-index.aspx)*

Weather

A simple, consistently worsening trend across weather measures could not be identified.

Year	Weather Conditions	Avg. High	Total Rain	Avg. Wind	Peak Gust	Thunder Days	Days ≥90°F
2023	Moderate weather	78.1°F	27.31 in.	6.42 mph	63.1 mph	38	35
2024	Higher storm activity	78.5°F	23.10 in.	6.53 mph	53.0 mph	38	45
2025	Heavy rainfall and storms	77.6°F	26.38 in.	6.53 mph	53.9 mph	34	29
2026	High temperatures and storm events	78.3°F	24.90 in.	6.49 mph	59.9 mph	34	35

Source: NOAA daily weather data for BWI March 1 - Oct 3 for 2023-2026 (https://www.ncei.noaa.gov/cdo-web/datatools)

Water Quality

Average dissolved oxygen remained relatively similar across the four comparison periods. However, the data also show recurring short-duration low-oxygen readings that are not apparent from the annual averages. In 2026, 104 monitored station-days included a dissolved-oxygen reading below 5 mg/L, and 52 included a reading below 2 mg/L, the highest number of below-2 mg/L station-days in the four-year comparison. Water temperature, salinity, turbidity, chlorophyll, and pH also varied materially among years, although the data do not demonstrate one uniformly worsening trend across all measures.

Year	Avg. DO	Station-days below 5 mg/L	Station-days below 2 mg/L	Avg. water temp.	Avg. salinity	Avg. pH	Avg. turbidity	Avg. chlorophyll
2023	8.02 mg/L	77	44	67.97°F	8.58 ppt	7.92	6.49 NTU	17.37 µg/L
2024	8.42 mg/L	102	45	70.50°F	4.40 ppt	7.95	6.91 NTU	21.79 µg/L
2025	8.69 mg/L	110	34	69.36°F	7.12 ppt	7.99	7.51 NTU	33.16 µg/L
2026	8.03 mg/L	104	52	70.00°F	8.3

Conclusions/Public Comment Support

My personal observations, conversations with others who have noticed the negative impact on local osprey populations and research of alternative possibilities have led me to believe that food shortages have a high probability of contributing to the negative impact on osprey populations. However, I also think that new implementations are most successful when approached moderately, with further changes supported based on analysis of results.

For the specific management options, I support:

Section 3.1, Option B, Sub-option B2, with phased implementation of the 20 percent reduction. I request an initial reduction of 10 percent from the current cap, followed by a public evaluation before proceeding to the full 20 percent reduction from that original cap.

3.2.1, Option B1, to distribute harvest more evenly across three seasonal periods, with allocations of 33, 33, and 34 percent. I support Section 3.2.2, Option B, to provide accountability for quota-period overages while allowing unused quota to move later in the season.

Section 3.3, Option B, requiring the Bay cap to be revisited every three years. In addition to that three-year review, I request annual monitoring reports and an explicit evaluation before further reduction phases. That evaluation should consider actual harvest changes, local forage availability, osprey feeding and nesting outcomes, environmental conditions, and economic effects on fishing communities. Monitoring, review dates, and criteria for further action should be established at the outset, allowing enough time to assess results while preserving the ability to respond sooner if conditions worsen.

Thank you for considering my observations and comments.

Categories: Menhaden 2 Auto Replied

Hello,

It is clear that the bunker stocks off NJ's coast is being negatively impacted. Sure there were days where the bunker was hard to find in the fall but it is much worse now than it has ever been. Only able to find peanut bunker for the entire summer. Went Striped Bass fishing yesterday and saw 0 bunker schools in around 30 miles. These fish are surviving on sand eels currently, so half of their normal diet during the fall.

Best,
Mike

Subject: [External] Subject Line: Addendum 1 Comment for the Public Record"

Dear Sir,

I am writing to express my strong support for Addendum II and the most restrictive options under consideration. Sufficient research has already been conducted, and the evidence clearly demonstrates the need for an immediate reduction or moratorium rather than further studies.

Decisions regarding Atlantic menhaden have far-reaching impacts on entire ocean ecosystems. Often referred to as the most important fish in the sea, menhaden serve as a vital food source for osprey, whales, dolphins, and striped bass, while also supporting commercial and recreational fisheries that sustain coastal economies. As a coastal resident, the decline in osprey populations and the broader health of our marine environment are matters of great concern to me.

Thank you for your time, attention, and consideration of this critical issue.

Sincerely,

Loretta Schwabenland
533 Oakmont Dr.
Myrtle Beach, SC 29579

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I am writing as a Maryland resident who has lived in St. Mary's County since the mid 1970's and has developed a deep personal connection to the Chesapeake Bay. I am an avid boater who has lived on the Patuxent River for almost 25 years and someone who spends considerable time on and around the Bay. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base. We have a pair of Ospreys who have a nest right off our pier and while they always produced 2-3 offspring every year, they have been unable to produce any offspring over the past 4-5 years.

I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, I urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management would provide a more precautionary approach and would better recognize the fact

that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.

There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

I respectfully urge the Commission to:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.

2. Establish firm seasonal quota periods for menhaden.

3. **Prevent excessive concentration of reduction harvest during the summer months.

4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.

5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.

We should not wait until the consequences are unmistakable before acting.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

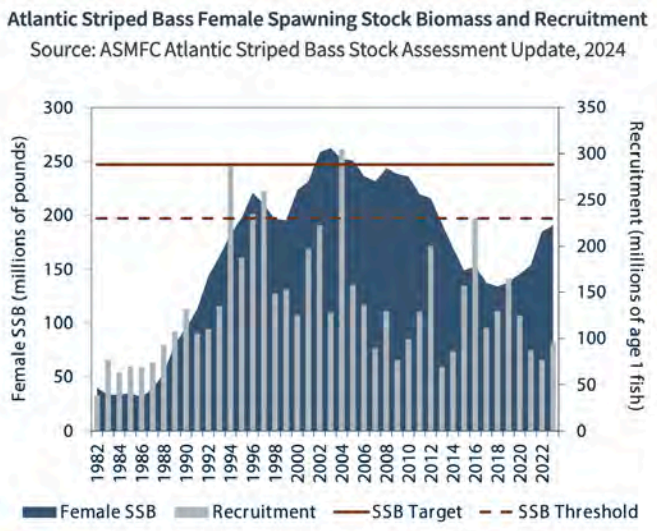
Sincerely,

Donald & Karol Selby
St. Mary’s County, Maryland

To: Atlantic Menhaden Management Board 9 September 2026
Subject: Atlantic Menhaden Draft Addendum II

First, I will offer some anecdotal evidence from my view as a recreational fisherman on the Lower Potomac River since 1997. As a test pilot at Patuxent River NAS, I have flown over the middle bay, from Calvert Beach, MD to just south of Smith Point, VA, for over 20 years and observed its changes in terms of Menhaden abundance. In my early years of flying out of Patuxent River NAS, I saw with amazement, large dark schools of menhaden, miles-long at times, with slashes of white through them from the predatory fish. In recent years, these schools have been reduced to small spots here and there and it is rare that I can pick-up predation on the schools at all as compared to the past. This would argue against the ASMFC 2024 statement that the stock continues to be successfully managed with the species not overfished nor experiencing overfishing.

Another anecdotal observation that I will offer is that in the early 2000's we recreational fishermen in our area on the Lower Potomac River, saw large numbers of schoolie rockfish (striped bass) that offered plenty of catch-and-release action for even the most amateur fishermen. That is not the case now. I also watched the precipitous decline of catches for larger striped bass in the spring, since I personally kept track of the catches for opening season in our neighborhood at Tall Timbers, MD for years. This agreed with the Chart from the ASMFC 2024 Annual Report showing the decline from 2012 to 2018. As the catch declined, I argued with my neighbors that we should release all large fish, and then eventually I argued to not fish at all in the early spring around the spawn. Since then, the regulations have changed to agree with my position. The regulators also placed a moratorium on targeting Striped Bass in August, and further restricted creel limits, which I whole-heartedly agree with. These measures have been big moves from what we were held to years ago. I fear they are still too little, too late in restoring the abundance of spawning stiped bass in the Potomac River. The correlation to menhaden reduction and the decline of the stiped bass population appears linked, in my mind, with the noticeable diminishment of menhaden in those years. Therefore, I must question why I have not seen similar magnitudes of restrictions in the reduction fishery.



One last anecdotal observation that I will offer, is that in fishing with charter captains from 1998-2012, we would pull-up to local pound-netters that were flush with mounds of menhaden that we would then purchase and use as chum for fishing. I see almost none of that abundance now in our local pound nets. A tradition that is on the wane, sadly.

Early morning October 2011 pound net in the Lower Potomac (the boat was full of menhaden)

I offer the following suggestions on the particulars of the Addendum II.

Section 2.1.
In the first paragraph, as a Statement of the Problem you refer to the Ecological Reference Point (ERP), which sounds a lot like a leading rationalization of why you might think the menhaden is not linked to declines in species such as Stripped Bass. Right up front this leads one to believe the Addendum will be biased in its approach. While overfishing is contributing to the decline in Striped Bass, the lack of abundance of menhaden should still be highlighted and referenced directly as a possible contributor to predator species decline. This would help address the chief concerns of those, like myself, that are concerned about that linkage, and which drove the concerns expressed in the ASMFC 2024 Annual Report. This last sentence in this paragraph, referring to the ERP, belongs elsewhere in the document as part of an analysis on correlation of Menhaden abundance to decline of predator fish stocks.

In section 2.1 you reference ASFMC 2024, but do not cite it in section 5.

In the second paragraph of section 2.1 you seem to scope the discussion to 3 issues, as management of the fishery, which may not adequately address one of the chief concerns from the ASMFC 2024 Annual Report, “Public concern about possible localized depletion of Atlantic menhaden in the Chesapeake Bay and the effects of the reduction fishery on menhaden predator species in the Bay.” This is in fact a statement of the Problem as many a fisherman sees it. The things I was looking for in the upfront discussion:

1. Correlation of menhaden numbers to predator fish stocks. If there is not strong data for this then a simple statement of acknowledgment that it is likely, or may be a factor, would help address the public concern. While acknowledging that many other factors such as overfishing has contributed to the decline of predator fish stocks like the striped bass, as discussed in the ERP, it is important to affirm that improving forage fish availability may have a positive impact on predator fish stock, and that this can have a positive effect on improving the lucrative sportfishing industry of the Chesapeake Bay. From ASMFC Memorandum April 23, 2025, the predators included in the ERP assessment model were chosen because of their dependence on menhaden as forage, though the dependence on menhaden varies by species with striped bass having the largest dependence (15.9% by weight; 11.7% by number). Additionally, other sportfish have been increasing in numbers in the Chesapeake Bay and placing demands upon forage fish. All of the species increasing in abundance in Chesapeake Bay are known to prey on menhaden, with the relative importance varying by season or ontogeny. Large spotted seatrout and Spanish mackerel had the highest diet composition of menhaden (31.5% and 40%, respectively) followed by small red drum (27.4%), and cobia (1.53%).
2. Acknowledge harvest restrictions for Bay Cap, and respectively TAC, that work in concert with the various recreational and commercial restrictions on predator fish stocks to support improving those predator fish stocks,
3. Then the options such as those discussed in the Addendum can be addressed and have better context.

I must ask why the chart in Figure 1 shows the number of landings for the bait fishery while the reduction fishery does not show actual numbers, which is argued for confidentiality. The depiction of this data in this way is questionable at best in that the less obvious note for figure 1 states that the reduction fishery takes 10 times that of the baitfish industry. This leads one to believe that the reduction fishery is either not reporting their numbers correctly or purposely exceeding their allocations. I would state why there is such confidentiality. I would also recommend you use similar timelines for comparison in Figure 1. Showing reduction fishery peaks of 1958, while the bait fishery is shown from 1985, distracts from the overall comparison and is at worst misleading. I think it irrelevant to point out the reduction levels in the early years which looks like another unnecessary rationalization for arguing against further restrictions.

Table 1. It is interesting to note that the TAC and Bay Cap were relatively the same from 2018 onward, even though there was a precipitous decline in the predator fish stock (striped bass) going into 2018. No action was evidently taken with respect to acting on the declining predator fish stocks.

Section 2.2.4
I would be interested in seeing pound net harvests from 2012-2018, toward correlating striped bass declines with Menhaden abundance. The Choptank data in section 2.2.5 would indicate that Menhaden abundance increased in 2018, but too late for helping recovery of predator fish stocks.

I would also be interested in a chart that compares the results of Figure 5, Bait fishery pound net harvest, to TAC and Bay Cap limits that are expressed in Table 1. It begs the question as to what data was driving the TAC and Bay Cap limits and how that process works.

I am extremely concerned about the 2022-2024 drop-off in CPUE found in Figure 5 and further confirmed in Figure 9. If this data is used as a proxy for determining menhaden abundance, this is going the wrong way for aiding in the recovery of predator fish stocks. It would also argue for major cuts in Bay Cap in upcoming years.

I find that the various metrics for determining TAC and Bay Cap are confusing at best. Is there a measure of the total actual landings of (bait fisheries + reduction fishery) compared to the TAC? Is there a measure of total actual landings of (bait fisheries in the Chesapeake Bay + reduction fisheries in the Chesapeake Bay) to the Bay Cap and is the Bay Cap predicated on data such as CPUE from pound nets.

Section 2.3
An offsetting argument for the loss of jobs and revenue in the reduction fishery should be offered. Here I would discuss the impact on the bait-fisheries, the recreational anglers, commercial fisherman and charter-boat captains with recovery of menhaden stocks and respectively the predator fish stocks. Recreational anglers provide a huge amount of income to various entities in the Chesapeake Bay area which would only improve with greater opportunities to catch target species. An economic impact study of 2016, commissioned by the Southwick Associates for the Striped Bass Coalition, showed that the striped bass recreational fishery supported $7.8 billion in total economic output toward the U.S. Gross Domestic Product. The fishery supported more than 68,000 jobs across the United States, ranging from bait and tackle shops to charter boat captains and coastal hospitality workers. The first paragraph hints at this but no further discussion is offered in reference to the benefits of improving predator fish stocks.

Section 3.
First paragraph: The reference to “harvest above the Bay Cap” would indicate that this is common and the penalty is to subtract from the next year’s limit. Are there other punitive measures for overharvest which might be mentioned?

I am concerned that the TAC is not representative of the menhaden stocks in the Chesapeake Bay and therefore tying a Bay Cap to the TAC may not be sufficiently restrictive to help in replenishment of menhaden stocks in the bay. If the majority of menhaden harvest is from the Chesapeake Bay, acknowledged in section 2.1 as the critical nursery for menhaden, then the Bay Cap should be predicated on a more direct measurement of Bay health such as a measure of total actual landings of (bait fisheries in the Chesapeake Bay + Reduction fisheries in the Chesapeake Bay) compared against estimated abundance with measures such as CPUE, and then translated into a Bay Cap. The Bay Cap then would be the biggest driver for determining the TAC, reverse of what has been proposed in some options.

As far as staggered quota periods, I would support such an initiative with regard to restricting the catch early in the season as compared to later in the season. The reasoning is simple in that fish size is proportionally smaller in the early season so that measures of weight will take more fish

in that season. One other standard that may apply here is the amount of by-catch that is taken in the different times of the year. I didn't see any discussion in that regard and would strongly recommend analysis of quota period with these factors in mind. With what I have gathered from the data I would expect that the one-time reduction in Bay Cap would look like 30-50% and ramp in quickly until further data shows a proper trending in abundance. This would argue for more periodic monitoring based on the magnitude of restrictions applied.

Atlantic Menhaden Management Board

Atlantic States Marie Fisheries Commission

Board Members,

I am a retired federal fishery biologist. For most of my career (1983-2015), I worked at NOAA's Beaufort Laboratory where I managed the fishery-dependent data bases for the Atlantic and gulf menhaden fisheries. I am writing to oppose any cuts to the Chesapeake Bay Menhaden Cap or to the Coastwide Menhaden Quota as proposed in Addendum II to Amendment 3 of the Atlantic Menhaden Fishery Management Plan. I am also opposed to creating quota periods for the purpose of distributing menhaden harvest in Chesapeake Bay. I am for maintaining the *status quo* of the coastwide quota on menhaden landings and also the Chesapeake Bay Cap.

As many senior Board members may recall, the original Chesapeake Bay Cap measure of 2006 was a toss-of-the-dart with no underlying scientific basis for the Cap value. The Cap approved by the Board in November 2006 of 109,020 metric tons (t) was merely an average of removals by the reduction fishery from the Bay for the previous five years. If the truth be known, much of the build up to the original Chesapeake Bay Cap was couched with the false accusations that the new fish oil facility at the Reedville (VA) menhaden factory would increase the fish plant's processing capacity and that Omega Protein Inc. was planning to move some of its vessels from the Gulf of Mexico to Reedville. Neither of which were true. In fact, Omega Protein was in the long-term process of reducing its Virginia fleet from eleven vessels in 2006 to seven by 2013. Likewise, the new oil plant was simply a refining facility for raw fish oil; it did not increase overall processing capacity of the factory. Subsequent reductions to the Cap after 2006 were equally arbitrary. Diminutions of the Cap to its current level of 51,000 t were again, simply an average of removals from the Bay for recent years with no biological basis.

Now, twenty years later and as a run-up to the Board's vote on Addendum II of the Atlantic Menhaden FMP, the disinformation abounds, much of which has to do with the health of striped bass in Chesapeake Bay and starving ospreys. I have listened to many sides of these Atlantic menhaden controversies during my career and post-career. However, there is one question which I have that no one seems capable of answering:

> If Atlantic menhaden are so important to striped bass in Chesapeake Bay, how did the Bay produce three of the most successful year classes (1993, 1996, and 1997) of striped bass in recent history during the 1990s?

Recall that during the 1990s, two menhaden factories existed at Reedville with a combined fleet of up to 24 vessels. Moreover, between 1990-1996 menhaden removals from the Bay averaged 148,100 t and reached 168,500 t in 1993[1]. This was a period when the stock assessments tell us that the menhaden population along the Atlantic coast, in terms of numbers of fish, was extremely low and recruitment of young-of-year menhaden

was poor to mediocre. Nevertheless, striped bass in Chesapeake Bay rebounded to near historically high levels. How was this so, if menhaden are so important to striped bass?

Likewise, a similar argument can be made regarding the starving osprey issue in lower Chesapeake Bay. From the data on osprey hatchling success which I have seen in print, osprey reproduction in the Bay was quite successful during the 1990s, a time when menhaden removals from the Bay were at record levels; all the while, the coastwide population of menhaden had contracted and juvenile recruitment was low. Again, if menhaden are so important to ospreys, what accounts for good hatchling success during the 1990s?

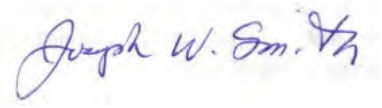
Currently, the Reedville menhaden fleet for reduction has been trimmed to six vessels (and one factory), plus two run boats. *In toto*, they account for 51,000 t or less of menhaden removed from Chesapeake Bay annually – *one-third of the removals from the Bay during the 1990s,* a time when both striped bass and osprey thrived. Clearly, there are other factors driving poor striped bass recruitment and poor osprey hatchling success.

In the near future, $4.5 million are to be available from state and federal sources for menhaden research in Chesapeake Bay. Indeed, a pilot tagging study is currently underway with assistance from the menhaden industry; if successful, a more robust tagging study should reveal much about menhaden ingress/egress into and out of Chesapeake Bay. Frameworks for aerial and hydroacoustic studies are also in the works; results of studies such as these will tell us much about menhaden seasonal abundance in the Bay. Perhaps, the Commission would be wise enough to recommend funding a stable isotope study of predator-prey groups in the Bay as was recently performed in the Gulf of Mexico[2]; results of the extant study indicated that gulf menhaden are not as important to food webs in the northern Gulf as many detractors of the menhaden fishery would have one believe.

In closing, I am asking the Board to seriously consider the pending menhaden research and 1) refrain from reducing the Chesapeake Bay Cap; 2) do not link the Chesapeake Bay Cap to coastwide quota reductions; and 3) avoid creating quota periods for Chesapeake Bay harvest. Moreover, let's not put the cart before the horse. Do not allow Addendum II to become a referendum via emails and postcards. Above all, follow the science. Let the Commission's preface on its web site guide your decision making:

> "…to protect essential marine species, ensuring vibrant fisheries, thriving communities, and resilient ecosystems, all through science-driven, cooperative management."

Sincerely,



Joseph W. Smith

Subject: [External] "Addendum 1 Comment for the Public Record"

Dear Sir:

"I support Addendum II and the most restrictive options."

My name is Mary Ann Steggles. I am a retired Professor living in Winnipeg, Canada, who studies Osprey Mortality. As you are aware, the quota for the Reduction catch of Menhaden is such that ospreys are either choosing to not breed or their chicks are dying on the nest. We are facing a worse threat of extinction than during the DDT crisis and many of us have been aware of this for several years. No one listened, until this year. There are many other species and many livelihoods at stake besides the staff at Reedsville, Virginia.

Please consider not another study but very restrictive limits or - I would propose - a complete moratorium by Reduction fishing of Menhaden by the Canadian corporations (or any others using gill netting) for at least ten years to allow the ecosystem to recover.

Yours Sincerely,

Mary Ann Steggles, PhD.

Subject: [External] My comments on menhadden addendum II

To the Atlantic States Marine Fisheries Commission,

I'm submitting my comments on Draft Addendum II for Atlantic Menhaden. As an angler, I want to see real protection for the Chesapeake Bay and the game fish and birds that depend on menhaden.

Here are the specific choices I back:

- **3.1 Chesapeake Bay Reduction Amount: Sub Option B4 (50% Reduction – 25,500 mt)** The Bay is the nursery for striped bass, bluefish, and weakfish. Slashing the current cap in half down to 25,500 metric tons is common sense. We need to stop large industrial operations from wiping out local schools of bait and starving out everything else.
- **3.2.1 Quota Period: Option B1 (Even Length & Even Harvest)** Breaking the cap into equal periods spreads out the commercial fishing pressure. It stops the fleet from hammering the Bay all at once early in the summer and leaving zero bait behind for the fall run.
- **3.2.2 Overages and Underages: Underage Sub Option 1 (Split Underages Evenly)** If they don't catch their full limit in the first period, splitting that extra allowance evenly into Periods 2 and 3 keeps the pressure steady. It prevents sudden, massive spikes in net effort later in the year.
- **3.3 Revisit Provision: Option B (Review Every 3 Years)** Things on the water change fast. Checking in on this cap every three years ensures management stays current instead of letting outdated numbers sit on the books for a decade.

If you clean out the bottom of the food chain, the whole fishery collapses. Please lock in these options to keep menhaden in the water and give our game fish and birds a fighting chance.

Respectfully,

Keyen Farrell

Subject: [External] Atlantic Draft Ammendment II

To the commission. Regarding Menhaden management.

I am not party to any of the scientific research, I am simply a concerned, citizen and fisherman. I've lived in Westport Connecticut for 23 years. 10 years ago I felt that the fishery was improving, I regularly saw schools of Bunker that covered acres of the water. The last three or four years, the situation has changed drastically. I thought maybe it was cyclical and then I learned about the reduction, fishery fleet, and the crazy volume of MENHADEN that they are extracting from the ocean. It is inconceivable that you can take that much biomass out of the ocean and expect it to recover and remain healthy. We are depleting our planet. You need to make the right choice for the future of this amazing ecosystem, you have an opportunity to stop the craziness. .

Thank you
Brian.

Subject: [External] Nov meeting

To Chair Cimino and the Atlantic Menhaden Management Board, re: Draft Addendum II.

My name is Denny Seabright. I'm a licensed guide operating out of Onancock, Virginia, on the seaside and bayside of the Eastern Shore. I make my living putting clients on striped bass, and striped bass make their living on menhaden.

I'm writing in support of Option 4, a 50% reduction to the Chesapeake Bay Reduction Fishery Cap to 25,500 metric tons, with seasonal distribution across 4 quota periods and automatic linkage to the coastwide TAC. At a minimum, the Board should adopt a 30% cut.

On the water here, we see localized depletion every spring. Omega's fleet can take the bulk of the Bay cap in May and June before menhaden have a chance to disperse up the Bay and into the tributaries. That leaves us in July and August searching for bait that should be everywhere, finding skinny, mycobacteria-marked rockfish, and watching osprey nests fail on the main stem. The Potomac River Fisheries Commission data and the osprey studies that have been entered into the record match exactly what we see from the poling platform.

You adopted Ecological Reference Points in 2020 for a reason, and your own 2025 benchmark said fishing mortality is above the ERP target for

striped bass forage. The law says you should manage toward the target, not just stay above the threshold. A 20% coastwide cut that leaves the Bay cap at 51,000 mt does not achieve that in the Bay. A 50% cut does, and splitting it into periods prevents the early pulse that causes the most damage.

For guides, bait shops, crabbers, and hotels from Wachapreague to Onancock, menhaden in the water are worth more than menhaden reduced into meal and oil in Reedville. I respect the reduction fishery's history, but Virginia is the only state that still allows industrial-scale reduction harvest inside an estuary nursery. New Jersey ended it for this exact reason.

Please approve the maximum reduction in Draft Addendum II this November. Keep more menhaden in the Chesapeake, spread the harvest through the season, and give striped bass, osprey, and the small businesses that depend on them a chance to recover.

Thank you for your time and for opening this to public comment.

Subject: [External] Draft Addendum, II

Dear Atlantic States Marine Fisheries Commission,

I am writing as a New Jersey resident after learning about the concerns surrounding menhaden and the unusually poor osprey reproduction reported in the Chesapeake Bay this year.

While I am not an expert in fisheries management, I have taken the time to learn more about this issue and have come to understand how important menhaden are as a food source for ospreys and many other fish and wildlife.

The 2026 Chesapeake osprey results have raised a very serious red flag. There are several factors that may be involved, including water temperature, salinity, weather, changes in where and when menhaden are available, fishing pressure, and other environmental factors. We don't yet know exactly how these factors are interacting, and that ambiguity warrants a precautionary approach.

That uncertainty is exactly why I am asking the Commission to take action now rather than waiting until the problem becomes difficult or impossible to reverse.

New Jersey has worked so hard to bring its osprey population back. I would like to see that success protected while we have the opportunity to do so.

I respectfully ask that the Commission support a meaningful reduction in the Chesapeake Bay menhaden harvest and a harvest schedule that leaves more fish in the water earlier in the season, while continuing to monitor the science and revisit the decision as more information becomes available.

To me, this is simply a matter of being careful with an important part of the food chain.

Thank you for considering my comments.

Sincerely,

Denise Monesteri

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board,

I am writing to comment on Atlantic Menhaden Draft Addendum II.

I strongly support reducing the Chesapeake Bay Reduction Fishery Cap by 50% to 25,500 metric tons (Sub-Option B4). The Chesapeake Bay is an extraordinarily important nursery and feeding area, and management of industrial menhaden harvest within the Bay should reflect the Bay's unique ecological importance rather than simply following coastwide harvest levels.
I also support Option B1 for the quota period, providing for even-length periods and even harvest; Underage Sub-Option 1, under which an underage from Quota Period 1 would be divided evenly between Quota Periods 2 and 3; and Option B for the revisit provision, requiring the Chesapeake Bay Cap to be reviewed at least once every three years.
I strongly oppose linking the Chesapeake Bay Cap to the coastwide TAC. The Bay Cap should function as an independent conservation measure for the Chesapeake. A coastwide increase in allowable harvest should not automatically permit increased industrial harvest inside the Bay.
At a coastwide TAC of roughly 112,000 metric tons, leaving the current 51,000-metric-ton Bay Cap in place could allow approximately 45% of the entire coastwide harvest to occur within the Chesapeake Bay. A 25,500-metric-ton cap would instead represent roughly 23% of that TAC and is much more consistent with recent historical harvest patterns.
Menhaden are a critical forage species, and their value extends far beyond their value as a commercially harvested commodity. I urge the Board to take a precautionary approach that recognizes the importance of abundant forage to the Chesapeake ecosystem, recreational fisheries, and coastal communities.
Please support a 25,500 metric ton Chesapeake Bay Reduction Fishery Cap and reject any mechanism that automatically links the Bay Cap to the coastwide TAC.

Thank you for considering my comments.

Subject: [External] Draft Addendum, II

Please reduce the allowable menhaden catch by at least 50%. They are being seriously overfished, endangering not only menhaden survival, but also osprey and marine animals who need to eat menhaden.
The Chesapeake Bay Foundation supports
-- 3.1C;e – a 50% reduction in the allowable Chesapeake Bay harvest and a 13.6% proportional cap on the coastal harvest, referred to as TAC
--3.2.1B2:3 which is a quota catch percentage of 25%, 25% and 50% during the three harvest periods. Delaying the largest harvest until the last catch period will hopefully provide some time for the menhaden to grow.
--revisit the catch limits in three years or sooner.

The menhaden population is crashing. We don't have time for years of research, while giant commercial operations continue to grab as much as they can.
Take action now while there's still time to stabilize the population.

Subject: [External] Draft Addendum II

Dear Sir:

Osprey populations are crashing and urgently need our attention and support now. If the current trends continue, the effect will likely be irreversible.

Research from the Center for Conservation Biology at the College of William and Mary shows that osprey reproduction in the salty portions of the Chesapeake Bay crashed to 0.25 chicks per pair in 2026. Studies of osprey nests on the Chesapeake Bay conclude that the osprey breeding efforts are now less successful than the years before the pesticide DDT was banned.

The absence of menhaden was observed by: American Bird Conservancy, Conserve Wildlife Foundation, Chesapeake Bay Foundation, Center for Conservation Biology at the College of William and Mary, osprey nest observers, charter boat captains and recreational fishermen from Maryland, New Jersey, New York and Connecticut. Many bait shops had little to no menhaden to sell and the fish they could obtain was usually smaller than in prior years. These smaller fish are called peanut bunker. New Jersey fishermen report seeing zero schools of menhaden this summer in coastal and bay water of New Jersey.

As a member of Bergen County Audubon I support the initiative by the Chesapeake Bay Foundation as outlined in their proposal to reduce the menhaden catch over the next three years and to help restore the osprey population which is under severe stress.

-- 3.1C;e – a 50% reduction in the allowable Chesapeake Bay harvest and a 13.6% proportional cap on the coastal harvest, referred to as TAC
--3.2.1B2:3 which is a quota catch percentage of 25%, 25% and 50% during the three harvest periods. Delaying the largest harvest until the last catch period will hopefully provide some time for the menhaden to grow
--revisit the catch limits at least in three years.

Subject: [External] Menhaden management

Categories: Menhaden 2 Auto Replied

I am submitting this email as my written comment on the draft addendum regarding possible reductions to the industrial reduction fishery in the Chesapeake Bay as well as the coastal waters along the eastern seaboard. I am a NJ recreational fisherman, charter boat mate and tackle shop employee. The removal of 100's of millions of pounds of menhaden by the reduction fleet essentially contracted by Omega Protein/Cooke Seafood has essentially eliminated the summer/fall migration of menhaden along the NJ, NY, and Long Island Sound coasts and tributaries. The few fish left never reach full adult size anymore prior to the Ocean Harvester's purse seine boats mopping them up. The lack of forage fish has affected fishing opportunities for the large NJ charter fleets, has caused serious economic problems for tackle shops that depend on them for bait sales as well as the commercial fishermen that harvest them for bait and now the issue is affecting the breeding success of ospreys. Omega is responsible for in excess of 70% of the menhaden harvest and the signs can not be more clear that they are removing FAR more menhaden than the stock can handle. I know harvest reductions of up to 50% are currently being considered and my question would be is that enough? Omega is currently fishing under quota due to the scarcity of the resource caused by years of overfishing. Cutting their quota leaves the possibility that they will still continue to land what they currently do. At the very least a 50% reduction of the reduction fishing quota along with staggering the harvest to allow the bait to reach the upper bay along with closing off some of the tributaries would be a possible starting point. Honestly a moratorium on the industrial harvest until more accurate scientific data is available would be the better option in my opinion. At least this could help protect what is left, once the resource is gone it will be too late.
Respectfully,
Stephen Saniewski

Subject: [External] Menhaden Limits

Categories: Menhaden 2 Auto Replied

In 2025, Connecticut Audubon's Osprey Nation recorded its lowest breeding success since the program launched in 2014. There is growing concern that Osprey populations along the Eastern seaboard are declining due to a lack of food.

By Aug. 1, 2025, out of 706 nests with up-to-date reports, 113 had failed — about 1 in 6. In the same timeframe this year, of 691 nests with up-to-date reports, 171 have failed — roughly 1 in 4.

The decline at Old Lyme's Great Island, once an Osprey stronghold, has been particularly severe. In 2024, 37 osprey chicks fledged at Great Island; in 2025, that number decreased to 27; in 2026, only five chicks fledged. This is an early warning that the fish population is severely declining and that overfishing of menhaden is likely a primary cause.

I ask that the Atlantic States Marine Fisheries Commission, which sets the ceiling for East Coast states on the number of fish that can be caught commercially, will consider any changes to commercial catch limits very carefully at its November meeting..

Subject: [External] PLEASE LISTEN TO CT AUDUBON, we care about OSPREY!!!!

Categories: Menhaden 2 Auto Replied

I am a Ct resident & I DO NO SUPPORT CHANGE THAT WILL AFFECT OSPREY AT ALL!!

Atlantic States Marine Fisheries
Commission is considering changes to the amount of menhaden that can be commercially harvested from the Chesapeake Bay. Connecticut Audubon is urging the commission to reduce the fishery cap by 50% to help ensure enough menhaden remain available for Ospreys and other wildlife.

Why does this matter?

There is growing concern that Osprey populations along the Eastern seaboard are declining due to a lack of food. Last year, Connecticut Audubon's Osprey Nation recorded its lowest breeding success since the statewide community science program launched in 2014 to monitor the birds.

This year is looking even worse.

By Aug. 1, 2025, out of 706 nests with up-to-date reports, 113 had failed — about 1 in 6. In the same timeframe this year, of 691 nests with up-to-date reports, 171 have failed — roughly 1 in 4.

The decline at Old Lyme's Great Island, once a former Osprey stronghold, has been particularly severe. Thirty-seven Osprey chicks fledged at Great Island in 2024. In 2025, that number decreased to 27. This year, only five chicks fledged.

Because Ospreys feed almost exclusively on fish, the Osprey Nation community science program serves as an early-warning system for the health of Connecticut's waters and the abundance of prey species like Atlantic menhaden.

The Atlantic States Marine Fisheries Commission, which sets the ceiling for East Coast states on the number of fish that can be caught commercially, will consider final action on the proposed changes at its annual meeting in November.

Subject: [External] Menhaden fishing limits

Categories: Menhaden 2 Auto Replied

I am a member of CT Audubon Society and a volunteer osprey steward. I am appalled that overzealous fishing has been allowed to significantly reduce the population of menhaden along the East Coast to the point where osprey are unable to successfully reproduce. This year I saw all 3 hatched offspring in my assigned nest die off.

This seems incredibly shortsighted and greedy to overfish to the point that it threatens the entire ecosystem. This is not sustainable. The osprey are sending us a message but the species being overfished will likely also be at risk. This is bad for all parties in the long run.

Action to reduce the number of fish caught must be taken urgently.

Arlington, VA 22201

Dear James,

I live in Milford CT where I can see the Osprey as well as hear them. I realized after observing a nest that the constant Osprey calling up in the nest seemed to be grief over the loss of their young.
I have also observed considerably less seagulls, cormorants. geese, ducks and all the smaller birds in our area in passed years alongside an increase in commercial fishing and additional watercraft. I already notice that the small numbers also decreases chances of connecting with each other for mating and not all birds are still breeders so the decrease in all wild life in my area just shows we are already at a critical stage for any of their survival. Saving the Osprey's food supply is a step forward for wildlife and this capping is a very important initiative.

Kind regards,
Rose Mikan

Subject: [External] Speaking up for starving osprey

Categories: Menhaden 2 Auto Replied

The Atlantic States Marine Fisheries Commission is considering changes to the amount of menhaden that can be commercially harvested from the Chesapeake Bay.

I live in Guilford CT and have enjoyed watching 3 osprey couples return to a marsh near my home to breed each year. I want their offspring to continue to thrive. Friends in other areas tell me that they are seeing fewer osprey couples returning, and I believe this is due to diminishing resources for the pairs to feed their offspring.

I agree with Connecticut Audubon that the commission should reduce the fishery cap by 50% to help ensure enough menhaden remain available for Ospreys and other wildlife.

Subject: [External] Menhaden Comment.

Categories: Menhaden 2 Auto Replied

To Whom It May Concern,

I am submitting this email as my written comment on the draft addendum regarding potential reductions to the industrial menhaden reduction fishery in the Chesapeake Bay and coastal waters along the Eastern Seaboard.

I am a New Jersey recreational fisherman and owner of Grumpys Tackle in Seaside Park, NJ. I have personally witnessed the dramatic decline in menhaden availability along the New Jersey, New York, and Long Island Sound coasts and in their tributaries. The removal of hundreds of millions of pounds of menhaden by the industrial reduction fleet, much of which is associated with Omega Protein/Cooke Seafood, has had a profound impact on the availability of this critical forage species.

The summer and fall menhaden migrations that were once a reliable and essential part of our coastal ecosystem have been severely diminished. The relatively few schools that remain often appear to be harvested before they have an opportunity to reach full adult size or move into the areas where they are most needed as forage. This has consequences far beyond the menhaden fishery itself.

It has also created significant economic problems for tackle shops including mine that depend on menhaden and menhaden-based bait sales. Most concerning, the consequences now appear to be extending to wildlife, including ospreys and other species that depend heavily on menhaden as a food source.

Omega Protein accounts for more than 70% of the menhaden reduction harvest. In my view, the continued scarcity of menhaden and the ecological and economic impacts being observed along the coast are strong indications that the current level of industrial harvest is placing excessive pressure on the resource.

I understand that harvest reductions of up to 50% are currently being considered. My question is simple: **Is 50% enough?**

The fact that the reduction fleet is currently fishing below its quota because of the scarcity of the resource should be viewed as a warning sign, not as evidence that additional reductions are unnecessary. Reducing the quota while leaving the industry capable of harvesting the same amount it is currently finding may not produce the meaningful recovery that the resource requires.

At a minimum, I believe a 50% reduction in the industrial reduction quota should be implemented, accompanied by management measures designed to protect the remaining menhaden during critical periods and in important nursery and forage areas. These could include staggering the harvest to allow

menhaden to reach the upper Bay and other areas where they provide critical forage, as well as establishing closures in selected tributaries and other sensitive areas.

However, I believe a stronger approach deserves serious consideration: **a moratorium on the industrial reduction harvest until more accurate and comprehensive scientific data are available to determine the true condition of the menhaden stock and the level of harvest the ecosystem can sustainably support.**

Menhaden are not simply another commercial commodity. They are a foundational forage species that supports striped bass, bluefish, tuna, sharks, whales, seabirds, ospreys, and many other components of the Atlantic coastal ecosystem. They also support an important recreational and commercial fishing economy.

We should not wait until the resource has collapsed before taking meaningful action. Once the menhaden are gone, reducing the quota on paper will not bring them back.

I respectfully ask that the Commission take a precautionary approach and implement substantial reductions in the industrial reduction fishery, with the ultimate goal of rebuilding a healthy, abundant menhaden population that can once again support the ecosystem and the fishing communities that depend upon it.

Thank you for considering my comments.

Respectfully,

Raymond Kerico

Subject: [External] proposed cap on Cheaspeake Bay fishery

Categories: Menhaden 2 Auto Replied

Dear Commissioners,

I strongly support the proposal to reduce the Chesapeake Bay menhaden fishery cap by 50% in order to protect the ospreys and other wildlife that rely on the menhaden for their survival. The catastrophic drop in successful osprey nests in Connecticut shows the impact of heavy fishing of menhaden. These fish are not used for human food but for bait, fish meal and fertilizer. Surely after having saved the osprey by restricting DDT, it would be cruel to let them starve in order to turn their food into fertilizer and fish food.

Sincerely,
Janice Trecker

Subject: [External] Reduction in menhaden fishery cap

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission:

There has been such an incredibly powerful increase in support of wildlife over the years as people witness species making a comeback thanks to the efforts of humans. The great resurgence of ospreys in Connecticut and especially around Great Island in Old Lyme, CT has been especially rewarding for so many.

Over the years, we have supported placement of nesting platforms for the osprey nests and experienced the joy of seeing babies occupying the nests. It was proof that people can help support wildlife and bring back endangered species.

We are greatly disturbed by the significant reduction in successful fledging of osprey in the state.

We encourage the reduction by 50% of the Chesapeake Bay menhaden fishery cap. This will greatly ensure enough menhaden remain for osprey and other wildlife. Thank you for your time.

Best,

Mary Ellen Kunz

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic Menhaden Management Board,

I am writing to urge the Board to implement the strongest possible conservation measures under Draft Addendum II. The tragic reality that osprey chicks are starving to death in their nests is a heartbreaking warning sign of a much larger ecosystem in crisis.

Ospreys are the canary in the coal mine. If the Board fails to act, the consequences of localized menhaden depletion will continue to ripple across the entire US East Coast marine food web:

- Menhaden are the vital heartbeat of the coastal ecosystem. Failing to significantly lower the harvest cap will continue to starve dependent apex predators, including striped bass, bluefish, weakfish, and marine mammals.
- The Chesapeake Bay serves as a critical ecological nursery. Allowing industrial purse-seine vessels to intensely harvest these waters during peak summer months creates immediate food deserts for nesting wildlife and migrating species alike.
- Managing this fishery purely for industrial yield while ignoring the collapse of dependent bird and fish populations threatens the long-term biodiversity and economic health of the Atlantic coast.

Please prioritize true ecosystem-based fisheries management. I strongly support Option B (a 50% reduction in the Chesapeake Bay harvest cap) and strict seasonal trimester splits to protect wildlife when they are at their most vulnerable.

Thank you for your time and for considering public input on this vital conservation issue.

Sincerely,

Amelia Longcroft

Subject: [External] Menhaden commercial reduction

Categories: Menhaden 2 Auto Replied

Sept. 9, 2026

Osprey chicks are starving to death. This is completely unacceptable. I support fisheries and keeping a healthy and balanced environment is important to me. Overfishing for profit to make fish oil, fertilizer and chicken feed is not acceptable. The cost is too high for all those species that depend on Menhaden for life itself. Menhaden should be a cherished species. I'll give up my fish oil supplement to keep the Menhaden fishery strong in the Chesapeake Bay and along the Eastern Seaboard. And I'm not the only one. When people become aware of how menhaden is being overfished and the products and companies that are profiting from this, they will act. Including publicizing the environmental consequences, like baby Osprey dying, and naming the responsible parties. Please reduce the number of Menhaden that can be taken for commercial use. This is a wise decision. One that supports multiple species not just immediate commercial greed. If commerce wants to take more menhaden, they should work to clean and environmentally support the Chesapeake Bay and Eastern Seaboard so more Menhaden can be supported and harvested. But what we take should always be in balance with what other species need too. Please diminish the tonnage of Menhaden commercial enterprises can harvest.
Thank you,

Dear Members of the ASMFC,

I hold a MA commercial fishing permit and an HMS charterboat/headboat permit.

I am on the water off cape cod 50+ days per year.

Menhaden are clearly overfished and overfishing is occurring, They are a pivotal forage species for predatory gamefish, namely striped bass (over fished) and bluefin tuna.

We need to protect the menhaden from over harvest.

I fully support a 50% reduction in the current Bay Cap and a 50% reduction in the Coastwide TAC.

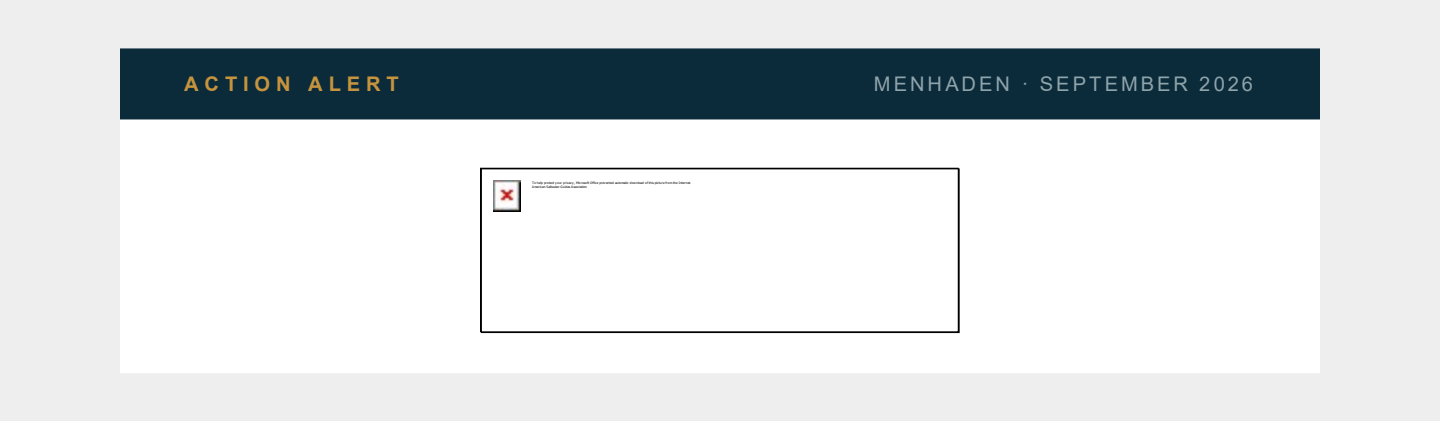
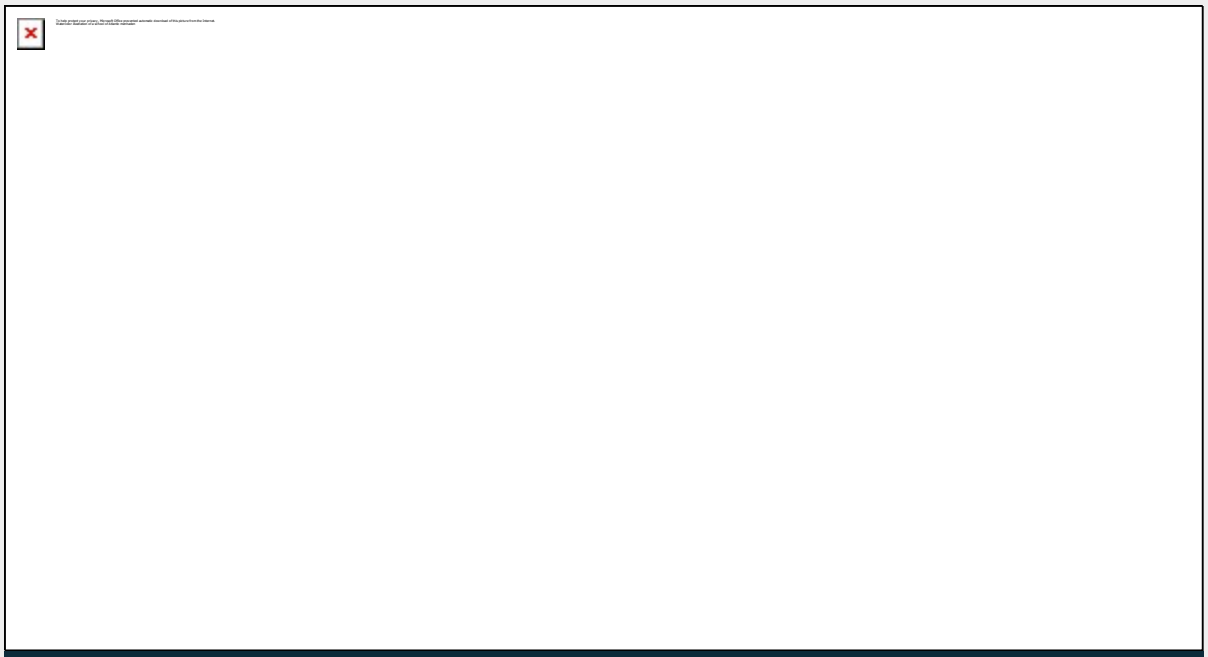
Subject: Action Alert: Menhaden Addendum II





COMMENT PERIOD OPEN THROUGH OCTOBER

DRAFT ADDENDUM II & THE COASTWIDE TAC

ASMFC has released **Draft Addendum II to Amendment 3** of the Atlantic Menhaden Interstate Fishery Management Plan for public comment. The comment period runs through October, and the Menhaden Board will consider final action at the Commission's Annual Meeting in November 2026.

What we are seeing along the Atlantic Coast and in the Chesapeake Bay is extremely concerning — not only from a fisheries management perspective, but for the communities, stakeholders, and anyone who depends on the future of these historic fisheries. Menhaden face a grossly overestimated assessment, the commercial fishery has seen consistently below-average harvests, and other important fisheries are declining.

This is the decision point. Below are ASGA's recommendations and every way you can weigh in.

New to this fight? Our summary of **how the fishery reached this point** covers the assessment error, the Bay Cap history, and everything else on the table this November.

WHERE WE STAND

ASGA RECOMMENDATIONS

ASGA supports the following alternatives for the Chesapeake Bay Cap as ecologically and socioeconomically appropriate — to reduce the risk of overfishing and promote resilient futures for the resource and its communities.

SECTION 3.1	CHESAPEAKE BAY REDUCTION AMOUNT	**Sub Option B4 — a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.**
SECTION 3.2.1	BAY REDUCTION FISHERY CAP QUOTA PERIOD	**Option B1 — Even Length & Even Harvest.**
SECTION 3.2.2	QUOTA PERIOD OVERAGES AND UNDERAGES	**Underage Sub Option 1 — an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.**
SECTION 3.3	BAY REDUCTION FISHERY CAP REVISIT PROVISION	**Option B — The Chesapeake Bay Cap will be reviewed at least once every three years.**

DON'T FORGET THE OCEAN

THE COASTWIDE TAC

To correct the assessment error, the coastwide total allowable catch was cut 20% for 2025, from 233,550 mt to 186,840 mt. But 2024 harvest was only 186,155 mt — so the reduction produced no real decrease in menhaden removals. A paper reduction, championed as a win.

Meanwhile, the sea herring fishery has collapsed. Maine's commercial menhaden bait fishery is catching over 900 mt a week this summer and has made clear it can ramp up to fill the lobster fishery's bait needs, estimated at 36,287 to 45,359 mt a year — not far off the entire current Bay Cap.

This fall, the TAC must be reduced by at least 30%, from 186,840 mt to 130,788 mt. Ideally it should be reduced by 50%, to 94,420 mt. These are the only options that keep the fishery from operating at a 100% probability of overfishing.

READ THE FULL BREAKDOWN

Read Draft Addendum II (PDF)

TAKE ACTION

HOW TO SUBMIT COMMENTS

Comments on the coastwide TAC should be emailed to ASMFC and should accompany your Addendum II comments on the Bay Cap. Personal messages are likely to have more impact than form letters.

I work daily chartering out of Saco, Maine. Menhaden are rarely seen, and this has been the case throughout my last two charter seasons. I observed two schools this entire summer, each of approximately 15 yards in diameter. I have completed 105 charters so far this season.

Maine saw large scale harvesting in the early 2000s and reacted quickly with aggressive rule making. Harvesting is small scale and the catch is used locally for lobster bait.

Maine is taking their fair share, and nothing more. All of the Atlantic states need to eliminate large scale harvesting in each respective state's waters. Time is running out!

Subject: [External] Menhaden Addendum II

Categories: Menhaden 2 Auto Replied

The decline in the Menhaden fishery has negatively impacted fisheries up and down the eastern sea board. This combined with a collapse in the sea herring fisheries is a failure in fisheries management across the board.

Menhaden biomass assessment is grossly over estimated. The 20% cut in total allowable catch in 2025 reduced TAC from 233,550 MT to 186,840 MT but the 2024 harvest was only 186,155 MT so it was meaningless.

Total allowable catch should be reduced by 50% to 94,420 MT.

I support the American Saltwater Guides Association recommendations of a 50% reduction in the current Chesapeake Bay cap to 25,500 MT and the cap should be reviewed at least once very three years.

Subject: [External] Atlantic Menhaden

Categories: Menhaden 2 Auto Replied

Dear Commissioners,

I am submitting this comment in response to your recent request for input from recreational fishermen regarding the current state of our coastal fisheries and the management of Atlantic menhaden. I have fished Jones Inlet and Jones Bay—by boat and from shore—for more than twenty-five years. Over that time, and especially during the past three years, I have witnessed a dramatic decline in both the abundance and diversity of fish species that have historically defined this fishery.

The downturn is not limited to a single species. Bluefish, striped bass, summer flounder, winter flounder, and black seabass have all declined sharply. Even non-target species such as horseshoe crabs, searobins, and stargazers—once common indicators of a healthy, functioning estuary—have become scarce. A decade ago, it was routine to see fifty or more boats drifting for fluke between the Jones Inlet Jetty and the Meadowbrook Bridge on a typical summer Saturday. For the past three years, that number has dwindled to only a handful. Bluefish and striped bass now appear for less than a week each season. Fluke are overwhelmingly undersized, and a single keeper has become a noteworthy event among regular anglers. I have not encountered a winter flounder in six years.

Based on long-term, firsthand observation, I believe these declines are directly linked to the diminishing availability of Atlantic menhaden—the primary forage species for bluefish, striped bass, and many other predators. The absence of bunker has fundamentally altered the ecosystem of Jones Inlet and Jones Bay. Predator species are food-stressed, bait concentrations are inconsistent or absent, and the broader ecological community shows signs of collapse.

For these reasons, I urge the Commission to adopt **meaningful, well-designed restrictions on commercial menhaden harvest**, particularly reduction fishing, which removes vast quantities of forage from the coastal ecosystem. Any attempt to rebuild predator fisheries without first ensuring adequate menhaden biomass will be ineffective. In my view, failure to act decisively now risks an irreversible decline in the fishery and the loss of a resource that has supported generations of anglers, coastal communities, and wildlife.

Thank you for considering my comments and for your continued work on behalf of our shared fisheries. I hope my observations help illustrate the seriousness of the situation and the urgent need for precautionary management of Atlantic menhaden.

Respectfully,

Michael Ginex, Lynbrook, NY

Subject: [External] Menhaden TAC

Categories: Menhaden 2 Auto Replied

Sent from my iPhone. I am a charter captain in the Cape May New Jersey area for 32 years and rarely see a school of Menhaden whereas in the past, I would see many many schools of Menhaden. Also, in the late summer, my Marina would fill with juvenile Manhattan, but now the schools are far and few between. I also noticed a lack of Peregrine Falcons in the areas where I normally see them which I strongly suspect, is due to the lack of feeding opportunities on the bunker

Dear Members of the Atlantic Menhaden Management Board,

I strongly support ASGA's recommendations for Draft Addendum II.

Specifically, I support **Sub Option B4**, reducing the Chesapeake Bay Cap by 50%, from 51,000 to **25,500 metric tons**, along with **Option B1**, establishing even-length and even-harvest quota periods. I also support **revising the Bay Cap every three years** to ensure it continues to reflect the best available science.

Thank you for taking action to protect this vital resource.

Sincerely,
Josh

Enough with letting Cooke, Inc. and Virginia desimate the osprey population in the Chesapeake Bay. This is such a flagrant abuse of the mission of the ASMFC. Shame on you. This is a repeat of the DDT assault on the bald eagle. The osprey which used to nest near our home on the Choptank River have disappeared.

If you are not too busy accepting bribes from Ccoke, Inc.'s henchmen, could you just possibly reply to a taxpayer who pays your salaries and expenses?

I am submitting a comment in favor of the MOST conservative management regime to limit the commercial menhaden harvest and encourage the regrowth in population of these fish at the most rapid rate possible. Menhaden have been over harvested, their population is too low, and they need a break to recover. Half measures are not enough. These fish form a critical base in the food chain. We humans—especially our commercial fisheries—need to leave some for other species and the future.

Matt

Subject: [External] Public Comment – Atlantic Menhaden Management

Categories: Menhaden 2 Auto Replied

To the Atlantic Menhaden Management Board,

I am writing to strongly support significant reductions in Atlantic menhaden harvest, both in the Chesapeake Bay and coastwide.

Menhaden are not simply another commercial fishery. They are a critical forage species supporting the entire Atlantic marine food web. Removing them at industrial scale necessarily reduces the food available to striped bass, bluefish, tuna, sharks, and countless other predators.

As a recreational angler, I am increasingly concerned that the effects of removing this foundational baitfish are becoming visible on the water. The health of our fisheries cannot be separated from the health and abundance of their forage base.

The recent 20% coastwide TAC reduction also does not appear to have meaningfully reduced actual harvest. A management measure that reduces the allowable number on paper while allowing essentially the same quantity of fish to be removed is not a meaningful conservation measure.

I therefore urge the Board to adopt a 50% reduction in the Chesapeake Bay cap, implement measures that prevent concentrated harvest in the Bay, and reduce the coastwide TAC by at least 30%, with a 50% reduction being preferable.

I understand that these decisions affect commercial fishermen and coastal economies. However, maintaining maximum short-term harvest of menhaden at the expense of the forage base risks damaging far more valuable fisheries and coastal economies over the long term.

Please prioritize the health and resilience of the entire ecosystem over maintaining unsustainable levels of menhaden removal.

Thank you for considering my comments.

Ben

Subject: [External] Public Comment on Atlantic Menhaden Management – Support for Meaningful Harvest Reductions

Categories: Menhaden 2 Auto Replied

To the Atlantic Menhaden Management Board,

I am writing as a recreational saltwater angler to express my strong support for meaningful reductions in Atlantic menhaden harvest, including the management measures outlined by the American Saltwater Guides Association.
I strongly support a 50% reduction of the Chesapeake Bay reduction-fishery cap, evenly distributed quota periods, appropriate treatment of underages, and a mandatory review of the Bay cap at least every three years. I also support reducing the coastwide TAC by at least 30%, with a 50% reduction being the more responsible course of action given the current uncertainty and the history of overharvest.

This is not simply an argument about one commercial fishery versus recreational fishing. Menhaden are a foundational forage species in the Atlantic ecosystem. Removing enormous quantities of them from the water has consequences far beyond the menhaden stock itself. They are food for striped bass, bluefish, tuna, weakfish, cobia, sharks, seabirds, and numerous other species. When the abundance of a critical forage species is reduced, the effects propagate throughout the ecosystem.

As a recreational angler, I believe those effects are already becoming apparent on the water. We are seeing declining abundance and availability of other valuable gamefish and sustainable food-fish species, and it is increasingly difficult to ignore the connection between the removal of a critical baitfish and the condition of the predators that depend upon it. Recreational anglers may not have the same economic leverage as large commercial fisheries, but we experience the consequences of these decisions directly every time we go fishing.

What concerns me particularly is that the recent coastwide TAC reduction appears to have been largely a reduction on paper. The TAC was reduced from 233,550 metric tons to 186,840 metric tons, yet the 2024 harvest was approximately 186,155 metric tons. In practical terms, the nominal reduction did not produce a meaningful reduction in the amount of menhaden actually removed from the ecosystem. That is not sufficient.

Management should not be structured around maintaining the maximum possible commercial harvest while attempting to justify that harvest with an uncertain stock assessment. The documented error in the natural mortality estimate is especially concerning because it resulted in an overestimation of stock productivity and an underestimation of fishing mortality. When the underlying assessment has been shown to have substantially underestimated the pressure being placed on the stock, the appropriate response should be precautionary—not to continue harvesting at essentially the same level and hope the assessment is correct this time.

I also believe the Chesapeake Bay deserves specific consideration rather than simply being treated as an interchangeable component of the coastwide fishery. The Bay is an enormously important nursery and feeding environment for menhaden and for the predators that depend on them. Concentrating intense reduction-fishery effort in a relatively small geographic area creates the potential for localized depletion that a coastwide assessment can easily fail to capture.

For these reasons, I urge the Board to adopt the proposed 50% reduction in the Chesapeake Bay cap and the associated measures that distribute harvest more evenly through time. I also urge the Board to reduce the coastwide TAC by at least 30%, and preferably by 50%, rather than accepting another nominal reduction that does little to change actual removals.

I understand that fisheries management involves legitimate economic interests and difficult tradeoffs. But those considerations cannot justify continuing to remove a foundational forage species at levels that jeopardize the broader ecosystem and the fisheries that depend upon it.

The long-term economic value of healthy recreational and commercial fisheries is far greater than the short-term value of maximizing menhaden harvest today. If we deplete the forage base, we ultimately undermine the striped bass, bluefish, tuna, and other fisheries that support recreational anglers, charter captains, tackle businesses, marinas, tourism, and coastal communities throughout the Atlantic states.

I therefore ask the Atlantic Menhaden Management Board to take the more precautionary course and implement substantial, meaningful reductions in both Chesapeake Bay and coastwide menhaden harvest.

Protecting menhaden is not just about protecting menhaden. It is about protecting the entire ecosystem and the fisheries, businesses, communities, and recreational traditions built upon it.

Thank you for considering my comments.

Sincerely,
Benjamin Masse

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic Menhaden Management Board,

I am writing as an active Chesapeake Bay boater, recreational angler, and coastal resident to express my strong support for aggressive, precautionary management under Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden.

Atlantic menhaden are the ecological keystone of the Chesapeake Bay estuary, serving as the primary forage base for striped bass, bluefish, weakfish, marine mammals, and breeding ospreys. While coastwide stocks outside the Bay may show stability, localized depletion within Chesapeake nursery waters is an urgent crisis that directly threatens recreational fisheries and avian survival.

I urge the Board to adopt the following specific management options:

- Issue 1 – Chesapeake Bay Reduction Fishery Cap: Option C1e. Tying the Bay Cap directly to the total commercial coastwide TAC at a reduced rate of 13.6% (an initial cap of 25,500 metric tons) creates a 50% reduction. This is an essential step to prevent localized overharvest and move industrial reduction purse-seining into open federal waters.
- Issue 2 – Quota Timing within the Chesapeake Bay Cap: Option B2 (Seasonal Harvest Distribution: 25% / 25% / 50%). Splitting the cap into distinct seasonal windows prevents aggressive harvesting during peak warm-weather months, leaving vital forage in place during critical feeding and nesting periods.
- Issue 3 – Bay Cap Review Provision: Option B (3-Year Revisit). The Board should formally re-evaluate the Bay Cap every three years as new ecological and localized depletion science becomes available.

Thank you for your dedication to science-based, ecosystem-level management. Please protect the ecological foundation of the Chesapeake Bay.

Sincerely,

Rick Creveling

Subject: [External] Save our menhaden!

Categories: Menhaden 2 Auto Replied

There was NO bunker in the Long Island Sound this year, very few striped bass, and probably thousands of hungry brown sharks. Something must be done to fix this problem before it's too late.

I support the following alternatives for the Chesapeake Bay Cap as ecologically and socioeconomically appropriate — to reduce the risk of overfishing and promote resilient futures for the resource and its communities.

Chesapeake Bay Reduction Amount
Sub Option B4 — a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

Bay Reduction Fishery Cap Quota Period
Option B1 — Even Length & Even Harvest

Quota Period Overages and Underages
Underage Sub Option 1 — an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

Bay Reduction Fishery Cap Revisit Provision
Option B — The Chesapeake Bay Cap will be reviewed at least once every three years.

Sincerely,
Curt Nadeau

Arlington, VA 22201

Re: Public Comment on Draft Addendum II to Amendment 3, Atlantic Menhaden Interstate Fishery Management Plan

Dear Mr. Boyle and Members of the Atlantic Menhaden Management Board,

My name is Aaron O'Hearn. I have fished Narragansett Bay for years, and what I have watched happen there over the last five is the reason I am writing.

Menhaden used to be plentiful in the upper Bay. I did not have to look for them. A few years ago I started finding fewer. The year after that, fewer still. This season I have not found them at all — not scarce, not scattered. Absent.

I understand that one angler on one bay is not a stock assessment. But this is a consistent, one-directional change across five seasons on water I know well, and it is not what a well-managed forage fishery looks like from a boat. It also lines up with what the Commission's own record already shows: a stock whose abundance was overestimated, a coastwide reduction that reduced nothing, and mounting pressure from fisheries hunting for a replacement for collapsed sea herring.

CHESAPEAKE BAY CAP

Section 3.1 — Bay Reduction Amount: I support Sub-Option B4, a 50% reduction in the current Bay Cap, resulting in a cap of 25,500 mt.

Section 3.2.1 — Quota Period: I support Option B1, Even Length and Even Harvest.

Section 3.2.2 — Overages and Underages: I support Underage Sub-Option 1, splitting a Quota Period 1 underage evenly across Quota Periods 2 and 3.

Section 3.3 — Revisit Provision: I support Option B, reviewing the Bay Cap at least once every three years.

THE COASTWIDE TAC

I urge the Board to treat the coastwide total allowable catch as the central question this November.

The 2025 action cut the TAC from 233,550 mt to 186,840 mt — a 20% reduction on paper. But 2024 harvest was 186,155 mt. The new ceiling was set essentially at the previous year's landings. That action corrected an assessment error without removing a single metric ton of actual harvest, and it should not be carried forward as though it were a conservation measure. It was a correction. The conservation decision is still in front of the Board.

Two things have changed since then, and both argue for a real reduction rather than another nominal one.

First, states are already rationing. In Massachusetts, the Division of Marine Fisheries closed the 2026 Episodic Event Set Aside Fishery and resumed the Quota Managed Fishery on September 1 with less than 98% of the state's annual menhaden quota remaining. That triggered an in-season cut of the commercial trip limit from 25,000 pounds to 6,000 pounds, plus a prohibition on carrier vessels, mandatory barrel or tote storage, and a 450-foot purse seine cap. A state one bay over from me is restricting menhaden harvest by emergency regulation in the middle of the season. That is not what surplus looks like.

Second, demand is climbing fast. With the sea herring fishery collapsed, menhaden is absorbing the shortfall. Maine's commercial bait fishery has been landing over 900 mt per week this summer and has signaled it can scale to cover the lobster fishery's bait needs, estimated at 36,287 to 45,359 mt annually. A single substitution of that size approaches the entire current Chesapeake Bay Cap. Pressure at that scale will not stay politely inside one state's ledger.

I therefore ask the Board to reduce the coastwide TAC by at least 30%, from 186,840 mt to 130,788 mt. I would support a 50% reduction, to 94,420 mt. Anything less keeps this fishery running at an unacceptable probability of overfishing at exactly the moment demand on the resource is accelerating.

Menhaden are forage. The striped bass, bluefish, tuna, whales, and birds that make this coast worth fishing all depend on them, and the guides, tackle shops, and coastal businesses depend in turn on those fish showing up. I would like to see menhaden come back to the upper Bay. That will not happen while the coastwide quota stays set at a number the fish cannot support.

Thank you for considering these comments.

Respectfully,

Aaron O'Hearn

Subject: [External] Critically important to reduce Menhaden fishery cap

Categories: Menhaden 2 Auto Replied

I urge the commission to reduce the fishery cap by at least 50% to help ensure enough menhaden are available for ospreys and other fish and wildlife. I monitor several nests here at the mouth of the CT River and all had 1 or 2 chicks, all but 1 starved.

The fishing at the mouth of the river was the worst it has been in my entire 35 years of fishing these waters. All because there was no menhaden to attract them.

Please help fishermen and the ospreys that depend on menhaden being plentiful in our waters. It was awful watching these birds starve.

Subject: [External] Draft Addendum II and the Coastwise TAC for Atlantic Menhaden

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

I'm writing today because of my concerns for the Draft Addendum II and the Coastwise TAC for Atlantic Menhaden and to explain the importance to our fisheries, our lifestyles and our general ability to support the marine food web. It doesn't take rocket science to understand gamefish—they like comfort, a steady source of food and every now and then, they want to reproduce. They're kind of like your typical male.

The essential component to that equation is a steady source of food. Where the food is plentiful, the gamefish, birds, crabs, the entire food web flourishes. Atlantic menhaden are a critical source of food for all our fisheries and the trickle down through the marine web. Where we see declines in the menhaden population, we see declines not just in gamefish, but in seabird life, herons, crabs, shrimp—the entire marine food web. Many of these trickle down species are also essential components to the food web, and their decrease further exacerbates the loss of marine life in that area.

We have more people on the water than ever, all competing for the same access to these fisheries, and all equally important, but without oversight of the menhaden stocks, we are already seeing major declines. That's a sign we're over harvesting the species. Even the commercial take is down, which again, is another sign of the decline of the resource.

It is imperative that you take action to protect Atlantic menhaden and manage the species in a sustainable way so that we don't see a total collapse of the species, the fisheries, the food web and the entire trickle down of marine life. Erring on the side of caution should be your mantra—that's how you would do it if your personal food source was being impacted. All the species involved in the Atlantic menhaden food web are critical to our economics, our lifestyles, our food sources and our state of mind.

I implore you to enhance your protection of Atlantic menhaden by implementing a 50% reduction in the current Bay Cap to 25,500Mt. And reviewing the Bay Cap every two or three years, implementing even length and harvests using the quota period and whenever there is an underage in Quote period 1, the quotas be split evenly and rolled over to Quota Periods 2 and 3.

The health of our fisheries are essential to the health of our fisheries, which determines my ability to make a living as a fishing guide, to live in a coastal environment that is thriving with wildlife and to support my ability to support my family and cherish what it is about where we live and why we live here. Over 60% of the population in this country lives along the coasts. There's a reason for that—we are drawn to the water and to the wildlife. To lose it in the name of profit and greed would be a shame.

Thank you for your time and efforts,

Mike Holliday

Categories: Menhaden 2 Auto Replied

I am writing to express my concerns for the mismanagement of menhaden. Legislators work hard to manage our fisheries and continue to adjust sizes and limits. It is irresponsible to not manage forage fish. We must have controls over this extremely important forage fish. We are seeing numerous species effected by overharvesting and not allowing these fish to grow and reproduce. Not only are sport fish effected but mammals and birds are as well.
Please put controls in place and manage menhaden populations the same as sport fish.
Thanks
John Wachter

Subject: [External] Menhaden stock reduction

Categories: Menhaden 2 Auto Replied

To who it may concern…

I am a resident of Barnegat New Jersey who has enjoyed fishing along the New Jersey coast out of Barnegat Inlet. I have been fishing for over 50 years and have seen the recent decline in the past several years of a number of sport fishing species such as blue fish and stripers. I have also read about the drastic reduction in the menhaden stocks in the Chesapeake Bay area. Without a healthy, sustainable stock of Menhaden, we will see a continued decline in these vital sport fish stocks which are the backbone of the industry along the whole east coast. Please react NOW to reduce the commercial take of Menhaden. We have a sad history of wiping out other species, such as Atlantic Cod, that should teach us to react before it is too late. The economies of a number of east coast states depend upon a healthy sports fishing industry. We also must keep our oceans healthy and sustainable for future generations to come.
I hope you hear and consider the outcry of our sport fishing community.
With Sincere Regards
Fred Scalera

Subject: [External] Public Comment: Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

To the Atlantic States Marine Fisheries Commission,

I am writing to submit my public comments regarding Atlantic Menhaden Draft Addendum II to Amendment 3. As a stakeholder invested in the health of our coastal ecosystems, I strongly support enhancing protections for Atlantic menhaden.

Specifically, I favor management actions under Option B to significantly reduce the Chesapeake Bay purse seine fishery cap, alongside Option C to implement seasonal time and area closures during peak summer months.

Furthermore, as a local angler, I have observed firsthand that fishing in the Sandy Hook area has greatly declined recently. The complete absence of menhaden all summer is undoubtedly the primary reason for this downturn. We do not want commercial boats off our coast netting our vital food source and severely impacting our local fishery.

Menhaden are a vital ecological linchpin. Reducing localized depletion ensures a stable forage base for critical apex predators, particularly striped bass, which rely heavily on healthy menhaden populations to sustain their migration and recovery along the East Coast.

Thank you for considering my feedback and for your ongoing efforts to manage our marine resources sustainably.

Sincerely,
Steven Lienhardt

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Mr. Poston,

My name is Lorraine Fechtig, and I am a Virginia resident concerned about Chesapeake Bay menhaden, as well as the species and communities dependent on a healthy ecosystem. The Chesapeake Bay is changing and showing signs of severe stress—protecting foundational forage fish is one of the most effective ways we can help this struggling estuary by

- Cutting the industrial harvest cap inside the Bay in half (Option C1e).
- Spreading the remaining seasonal limits evenly across the spring, summer, and fall (Option D2).
- Revisiting the ecosystem data every 3 years (Option B)

Regarding the specific management options under consideration in Draft Addendum II, I request that the Board approve the following measures:

- **Section 3.1 (Bay Cap Amount):** I support **Option C1e** to reduce the Chesapeake Bay reduction fishery cap by 50 percent to protect our local food web from localized depletion.
- **Section 3.2 (Cap Distribution):** I support **Option D2** to distribute the harvest cap into three equal seasonal periods, preventing the industrial fleet from concentrating all fishing pressure during the vital spring and summer nursery seasons.
- **Section 3.3 (Revisit Provision):** I support **Option B** to ensure these management tools are strictly reviewed every 3 years for effectiveness.

Ensuring that enough menhaden remain in our waters is essential to the long-term health and productivity of the Chesapeake Bay. Please add my name and support to the public record in favor of these conservation measures.

Sincerely,

lorraine fechtig
Virginia

Subject: [External] Coastwide TAC and Addendum II Bay Cap

Categories: Menhaden 2 Auto Replied

Regarding the coastwide TAC, the ASMFC needs to cut catch by at least 30% The schools of bunker I no longer see are a clear indication to me that something is going on and action needs to be taken now. Regarding the Addendum II choices on the Bay Cap, I accept the choices advocated by the as well thought out and necessary for the protection of the fishery and athe massive food web it supports.

When I go to the beach, I don't smell bunker anymore, but what I do smell I fear are the ghosts of the carrier pigeon. Too little too late is the same as doing nothing and watching extinction play out in front of us.

Thank you for your attention,

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I am writing as a Maryland resident who has lived in St. Mary's County since 2023and has developed a deep personal connection to the Chesapeake Bay. I am an avid conservationist. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base.

I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, I urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management would provide a more

precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.

There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

I respectfully urge the Commission to:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.

2. Establish firm seasonal quota periods for menhaden.

3. **Prevent excessive concentration of reduction harvest during the summer months.

4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.

5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.

We should not wait until the consequences are unmistakable before acting.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

Sincerely,

Christine S. Grossman

To the Commission:
I've been made aware by CT Audubon that Osprey populations along the Eastern seaboard are declining due to a lack of food, as per their latest report.
I am urging the ASMFC to reduce the fishery cap by 50%, a precautionary measure to ensure that menhaden, a key foundation fish and a prime food source for Connecticut's Osprey, are not put in even greater jeopardy.

Even more so now, the numbers show that Osprey and other species that rely on menhaden do not have years longer to wait.

This year, Osprey Nation also saw a high number of nest failures and a severe drop in the number of nests that fledged three chicks. Of 679 total nest attempts, 40% failed. Failures include nests where incubation was unsuccessful as well as nests where chicks hatched but did not survive to fledging. Both types of failure can be associated with food stress, although weather, disturbance, predation, inexperience, and other factors can also contribute to unsuccessful nests.

Meanwhile, only 23 nests — less than 6% of all nests — fledged three chicks this year. In previous seasons, up to 20% fell into this category.

I urge you to act now while remaining open to stricter measures.

Thank you,
Barbara Harman
Concerned CT resident

Hello Atlantic Marine Fisheries Commission,
Stop permitting the dramatic overfishing of menhaden! You know it's wrong. How about NO harvest until Ospreys recover.
Also it is criminal to be bribed by Omega Protein. Do you want your legacy to be "This person was responsible for the slow extinction of an iconic Chesapeake Bay raptor"?

Hey ASMFC,

I am writing to say I strongly support passing Addendum II and reducing the Bay Cap to 25,500 metric tons. This is a critical area for so many valuable species and must be protected from overharvesting.

I also think that the Bay Cap should in no way be linked to the TAC coastwide. I strongly oppose linking the two, and think that the Bay Cap should stand at it's historical average of TAC and be considered standalone as such.

Thank you

Alex

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Hello -

My name is Joseph Esposito and I am a saltwater angler from Connecticut, where menhaden numbers are down significantly compared to prior years. This not only has negative impacts on our fishery, but our osprey population as well.

Regarding Atlantic Menhaden Draft Addendum II, I support:

- Fixing the Chesapeake Bay Reduction Fishery Cap at 25,500 metric tons.
    - At a coastwide quota near 112,000 metric tons, keeping the current 51,000-ton Bay Cap would allow roughly 45% of the coast's harvest to come from inside the Bay. A 25,500-ton cap is about 23%, in line with the 24% average since 2018.
- Rejecting every option linking the Bay Cap to the coastwide TAC.
    - Reductions to the Bay Cap are conservation for the Bay, and should be approached as such. Linking the Bay Cap to the coastwide TAC opens the door for geographic reallocations of unused quota and for increased harvest in the future.

I stand by the opinions of the American Saltwater Guides Association. Thank you for considering my public comment.

Joseph Esposito

Dear Members of the Commission,

I am writing to express my strong support for the draft addendum to cap menhaden fishing in the Chesapeake Bay.

Menhaden are a vital part of the Chesapeake Bay ecosystem, serving as an important food source for striped bass, bluefish, osprey, and other wildlife, while also playing an important role in maintaining the health of the Bay. Establishing a meaningful cap on menhaden harvest is a necessary step toward protecting this important forage fish and supporting a healthy, balanced ecosystem.

I respectfully urge you to adopt the draft addendum and support a responsible cap on menhaden fishing in the Chesapeake Bay.

Thank you for your consideration and for your continued efforts to protect the Chesapeake Bay.

Sincerely,
Katherine King

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle

I am writing as a physician and public health/ environmental protection and endangered species protection advocate, that strongly supports full protection for our public health and our oceans, our aquatic sea animal ecosystems from ocean and environmental pollution due plastic ocean pollution. It is very critical to understand that any ingestion of plastic pellets endangers our public health and the ocean health for our waters and our aquatic sea life.

At this time, I strongly support the fact that the menhaden fish continue to carry out some of the most important work in our oceans. These small, silvery fish serve as a crucial food source for aquatic fish and birds including ospreys and herons to whales and striped bass. These fish filter plankton from the waters off the Atlantic Coast as they feed. However, as climate change and ocean warming dangers continue to endanger survival for menhaden, concerns are growing about whether enough of these fish will remain to support the marine life and birds that depend on them.

I am aware that I am submitting this letter because the public comment period closes in a few days and regulators make their decision. I am aware that the Atlantic States Marine Fisheries Commission is deciding how much menhaden can be caught, and the outcome will influence the health of our coastal waters for years to come.

As an endangered animal protection advocate, I strongly support protection for the health of our oceans and coastal wildlife. To ensure this continued protection, I strongly urge the Atlantic States Marine Fisheries Commission to please strengthen how it manages Atlantic menhaden, which is a small but essential forage fish.

Please realize that sustainable fishing can coexist with a healthy, abundant menhaden population. However, achieving that balance requires management that fully accounts for menhaden's dual role which includes feeding wildlife and potentially influencing coastal water quality and the ability to be successful does not only depend upon traditional catch limits.

Please understand that Addendum II is a step in the right direction, However, it does not fully ensure that menhaden remains a healthy, abundant part of our coastal ecosystems.

To greatly increase these protections, I strongly urge you to please fully account for the crucial role that menhaden remain as a food source for birds, whales, and fish, and their role in filtering plankton for our coastal waters, in your management decisions. Please adopt strong, science documented management that preserves menhaden as a robust food source for its predators, while also expanding management tools to prevent excessive catch during critical times and areas, by distributing fishing pressure more evenly throughout the season.

At this time, I thank you for your consideration of my letter, my significant public health and environment protection concerns for Atlantic menhaden fish recovery and my recommendations. To ensure full protection for menhaden supplies in our sea waters, I strongly urge the Atlantic States Marine Fisheries Commission to please strengthen and commit to promptly updating menhaden management as new science and assessments become available. As an endangered fish protection advocate, I can document that the continued protection for Atlantic menhaden is too important and crucial at this time. Please strengthen protections for this vital fish before it's too late.

Sincerely,
Jean Marie Naples, MD-Ph.D.

Subject: [External] Atlantic Menhaden 2027-2028 TAC

Categories: Menhaden 2 Auto Replied

Commissioners - a very frustrated dad and recreational angler in New England here. I hate watching our fisheries decline before my eyes. It's getting exponentially worse every single year. Please do something to stop the madness.

I fully support:

- **Cut the coastwide TAC by 40%** to approximately 112,100 metric tons for 2027 and 2028, which the ASMFC's own science projects would still result in a 40% and 50% chance of overharvest during those years.
    - Effective management action is needed now. Delays would allow the current TAC (186,840 mt) to be used for the 2027 harvest season, enabling continued unsustainable Atlantic Menhaden harvests by the commercial fishery.
    - Set the TAC as a fixed tonnage for 2027 and 2028, not a formula that adjusts automatically. Do not defer it pending further analysis

- **Reject every option linking the Bay Cap to the coastwide TAC.** Reductions to the Bay Cap are conservation for the Bay, and should be approached as such. Linking the Bay Cap to the coastwide TAC opens the door for geographic reallocations of unused quota and for increased harvest in the future.

Sincerely,
Jeff Amorello

Hello,
I'm resident of the Chesapeake Bay region and spend a great deal of time on the bay, both on a kayak and on various nature trails along its shores year round. Over the last few years I've been horrified to watch what's happening to the bay osprey population, as well as the overall heath of the bay ecosystem due to the drastic reduction in the menhaden population. Not only is this a problem for the local ecosystem but I've also talked to many local fisherman and crabbers who have spoken about how deeply this has effected them as well, both in terms of the declining numbers of fish and crabs they're seeing and in the price of bait.
I'm originally from Maine, a place that has seen huge ecological and economic benefits from conservation based practices and decisions in fishing regulations, and can speak personally to how those practices best serve local ecosystems and the people who rely on them.
For all these reasons and more I'm reaching out to you to voice my strong support for the following options in Draft Addendum II:

- 3.1 Chesapeake Bay Reduction Fishery Cap Amount: Support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.

- 3.2 Chesapeake Bay Cap Distribution: Support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. Also, support option B which establishes quota period overage payback and rollover of unused quota within a fishing year.

- 3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

Thank you!

Best,
Katie Starbird-Tierney

AMFC,

Menhaden stocks have been poorly managed, resulting in commercial fishing harvest and quotas that have drastically reduced the viability of the species and the ecosystem that relies on their abundance.

I support the following for Draft Addendum II:

SECTION 3.1

CHESAPEAKE BAY REDUCTION AMOUNT

Sub Option B4 — a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

SECTION 3.2.1

BAY REDUCTION FISHERY CAP QUOTA PERIOD

Option B1 — Even Length & Even Harvest.

SECTION 3.2.2

QUOTA PERIOD OVERAGES AND UNDERAGES

Underage Sub Option 1 — an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

SECTION 3.3

BAY REDUCTION FISHERY CAP REVISIT PROVISION

Option B — The Chesapeake Bay Cap will be reviewed at least once every three years.

With concern and support for converative management measures,

Brian Sittlow

Westerly, RI

Please take into consideration the stock count and the over harvesting of the most critical baitfish in our ocean. The impact is far further than just financial. It will cause our local fisheries to loose billions. If we have no bunker, we have no tuna, no striped bass, no bluefish and no whales. Every single one of these animals contributes to the economy in a small or very large way. Making up a massive portion of economic impact. Much greater than a few company's pillaging a highly valued resource. Please consider what you are doing and cut the stock consumption. I haven't seen adult bunker in my home water in multiple years and the fishing reflects that. Please do something about this. God bless.

Categories: Menhaden 2 Auto Replied

To the ASMFC Commissioners,

I am an osprey nest steward in Connecticut and I have been monitoring nests since 2016. I have seen dramatic changes in osprey productivity this year. Nests that had multiple fledglings in the past had one or the nest failed completely. The Connecticut Audubon Society's preliminary report with 99% of the season's data compiled, osprey productivity stands at 0.87 chicks per breeding pair, down sharply from the previous record low of 1.26 in 2025.

In Rhode Island, only 38% of the 339 monitored nests had successfully fledged young. That's only 0.33 young per pair.
In 2025, Conserve Wildlife Foundation of New Jersey documented the worst breeding season in more than 30 years.
ospreys to maintain a stable population is 0.8 young per pair.

The Connecticut Audubon Society along with Oceana, The American Bird Conservancy, The National Wildlife Federation Action Fund, Conserve Wildlife Foundation of New Jersey, New Jersey Osprey Project. and others are stating osprey populations are in trouble This has been documented in recent years to be caused by a decreased availability of Atlantic menhaden to nesting ospreys due to industrial-scale harvesting in the Chesapeake Bay. Menhaden constituting three-quarters or more of the osprey's total prey especially when the chicks are young.

Adult ospreys are increasingly unable to locate sufficient menhaden resulting in starving chicks, nest failures, abandoned nests and chick and fledgling deaths.

It's time to act. I respectfully ask you to pause altogether or significantly reduce the Chesapeake Bay menhaden catch by 50%, spreading the harvest more evenly across the season, and linking the Chesapeake Bay cap to the Atlantic coast's total allowable catch.

Bringing up menhaden populations is one of the most effective ways that can be taken to maintaining a balanced and productive marine ecosystem and to restore osprey populations.

Please take the next critical step by protecting menhaden so that both wildlife and a healthy ecosystem can thrive.

Sincerely,

Laura Bastien
Waterford, CT

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

We strongly support reducing the Chesapeake Bay reduction-fishery cap by ***50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden*.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

We own riverfront property in Tall Timbers, MD. There are two Osprey nests on poles; one just up-river and one just down-river from our land. It is horrible to watch, this past three years, the Osprey chicks starve to death.

In addition to Osprey and their chicks, there are other types of marine life in the Chesapeake watershed that depend on menhaden for their survival. Watching the Osprey chicks die like this is visual evidence on the impact on other species that depend on menhaden in the Chesapeake watershed.

A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource. *It is both when and where those fish are removed that matter*.

One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users. The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism.

Please:

• ***Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually*.**

• ***Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.***

• ***Apply a precautionary management approach considering uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.***

• ***Consider the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just ONE Virginia based fishing company.***

The Chesapeake Bay is a complex and interconnected ecosystem, and menhaden are one of its essential links.

Please do not wait for further deterioration before acting. There is no time for additional five-year studies to delay the decision. The severe drop in Osprey nesting pairs and the lack of their surviving chicks will not replenish the species enough to survive that long.

We believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.

Thank you for your consideration.

Sincerely,

Scott and Melissa Stricker

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic Menhaden Management Board:

I am writing as a recreational angler from Marblehead, Massachusetts to urge the Board to adopt the strongest conservation measures in Draft Addendum II to the Atlantic Menhaden Fishery Management Plan.
Menhaden are the foundation of the Atlantic food web, and the science shows current harvest levels are leaving too few fish in the water, especially in Chesapeake Bay.

I support the following actions:

1. Cut the Chesapeake Bay reduction fishery cap by the full 50 percent. Only a full cut leaves enough forage in the Bay for striped bass, bluefish, weakfish, osprey, and the many other species that depend on menhaden.

2. Link the Bay cap to the coastwide catch limit, so that when the coastwide limit drops, the Bay cap drops with it. The Bay should not absorb a growing share of coastwide harvest when overall limits tighten.

3. Spread the Bay harvest across quota periods so the Bay is not stripped of menhaden in spring and summer, when predators need them most.

4. Reduce the coastwide catch limit by 40 percent to meet the science for 2027 and beyond. Without a significant cut, the fishery faces an unacceptable risk of overfishing.

I fish the waters off Massachusetts, and healthy menhaden runs mean healthy striped bass and bluefish seasons for all of us. Please act on the science and give this critical forage species the protection it needs.

Thank you for considering my comments.

Sincerely,
Will Danforth
Marblehead, MA

Dear Sirs,

The long standing model used by the Atlantic Coast Fisheries, the Maryland Department of Natural Resources, and even the U.S. Army Core of Engineers (to the extent they are engaged in the rubber stamping of permits) as they collectively profess that they can successfully manage the last 10% of the historical high fisheries annual catch data and records has been an absolute and abysmal FAILURE!

Currently, according to the 2025 Fisheries Catch records, the management of the Chesapeake Bay (including the Potomac River) fisheries has fallen to attempting to now manage the last one perfent (1%) of historical annual catch highs.

Given this decline, immediate action is necessary. I urge you to take an aggressive stance by reducing the Menhaden Annual Catch Limits by 75% for all commercial enterprises for the next ten (10) years.

As a local citizen, I stopped purchasing a recreational sport fishing license over six years ago due to the severe depletion of Rockfish in our estuary. We need to Immediately lower Menhaden catch limits which is critical to restoring these populations.

Regards,
Charles F. Shilling

We are past due the time that the ASMFC should put a 50% reduction on the menhaden harvest by Omega Protein, Ocean Harvest. There is more than enough scientific evidence from endless studies linking Strip bass declines and now Osprey nest failures where Omega Protein operates. NOW is when the ASMFC needs to act. We have too many examples of fish species declining and subsequently other dependent species because of fishery mismanagement by industry and the ASMFC. An historic example is the collapse of the Cod fishery. And now the identical fishing technology is being utilized by Ocean Harvest up and down the Atlantic Coast and the Chesapeake Bay area. This industrial form of fishing is not sustainable! I am 76 and have witnessed too many species decline or go extinct. It is my responsibility to respond to these failures on behalf of future generations of all species. I am asking that the ASMFC and NOT Omega Protein assume the responsibility of putting in place a 50% reduction on mendaden harvest and also spread that harvest over the season to protect the reproduction and lives of dependent species. Sincerely Robert J. Cukla

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

To Whom it May Concern:

I am writing to express my strong support for a 50% reduction in the Chesapeake Bay Reduction Fishery Cap (Option B4/ reducing the cap to 25,500 metric tons). As an ecologist, I support seasonal quota periods as this just makes good ecological sense. As a concerned citizen who lives within the Chesapeake Bay watershed, I am concerned about the environmental and economic health of this large important body of water.

If we consider the osprey as an indicator of the health of the Bay, then we are failing miserably. The last several years have seen declining productivity and widespread nest failures. Industrial reduction fishing extracts over 100 million pounds of fish in a concentrated period over the summer. Any high school biology student knows that the removal of fish harms the food web and those species dependent on this food source. This reduction in fish also deprives watermen, anglers, and coast tourism economies of fair access.

Please support implementation of strict quota periods that distribute harvest evenly across the year rather than allowing an intense summer harvest. It's in the best interest of all species.

Thank you for your time and consideration,

Rita Allan

To whom it may concern,

This is not just our future at risk, but those of our children and grandchildren. If they want a chance at enjoying angling, and the natural world through this lens, and if we want to continue having enough food to eat, we need to listen to science and therefore I support:

cutting the Chesapeake Bay Cap by the full 50%

Linking the Bay Cap to the coastwide catch limit, so when one drops, the other does too

Spreading Bay harvest across quota periods so the Bay isn't stripped in spring and summer

Reducing the coastwide catch limit by 40% to meet the science for 2027 and beyond.

Please take this into account when making decisions.

Kind Regards,
Malena Thren

Subject: [External] Approve Draft Addendum II for menhaden management

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator Boyle,

An abundant menhaden population is crucial for keeping sportfishing relevant. Fewer menhaden means fewer gamefish, which in turn means fewer fishermen. There's no point in going fishing if fish aren't available, or so scarce that it's not worth the effort. The recent decision in CCA v. State of North Carolina relied on evidence that overfishing for a species reduces the population of that species AND other species. Please don't make the same mistake that North Carolina made. Some of those fish stocks may be permanently harmed.

Sincerely,

Michael Toth

I am a member of Osprey Watch and provide data on 5 nesting platforms. The fledgling rate was .025 this year. It has continually gone don't year over year from food stress. Our local anglers have noticed a big difference in fishing. The ducks aren't producing young, we used to have up to 30 ducklings in our creek every summer and this year we had two. We have less juvenile herons and less Megansere and buffoeheads in the winter. We need to protect the bay and limit menhaden catch near the coast. It doesn't make any sense to me to catch menhaden to turn it into fish food for farmed salmon either.

I urge all those involved to help protect the menhaden population. I live on the coast and have enjoyed watching the Ospreys come back year after year to their nests to rear their next brood. The thought that after overcoming near extinction to thrive and now to be at risk once again is heartbreaking. We need to look at this more than just an osprey problem. As we know a kink in the food chain sets off a domino effect which will in the long run effect everyone including the fishermen who rely on the larger fish to make a living.

I am in strong support of further reductions in the menhaden quotas to reduce the impact of harvesting on the menhaden population. Menhaden underpin the entire Atlantic coastal ecosystem, and it is essential that we do everything we can to maintain ample forage for the multitude of predators that rely on them, and support local economies. Whether starving osprey or declining populations of striped bass, we know something is wrong, and this action would surely improve the situation. In a world where this ecosystem is under threat from habitat loss, nonpoint source pollution, and climate change, protecting the forage base is something we have more control over to actually make positive change. Let's choose to make that high-impact action for the future of our waters. Please take steps to reduce the quotas as soon as possible. Thank you.

As someone who lives on the Massachusetts coast, it has been heartening to see decades of conservation efforts help osprey populations recover. I am therefore saddened to learn that ospreys in the Mid-Atlantic are struggling as one of their key food sources, menhaden, has declined. However, I am encouraged that the Atlantic States Marine Fisheries Commission is considering a significant reduction in menhaden catch quotas to help this important forage fish rebuild its abundance and commend the Commission for taking action.

As the Commission considers this reduction, I urge you to also examine how menhaden quotas are allocated along the coast. A more equitable allocation could help ensure that fishermen and lobstermen in coastal communities have fair access to this important resource and support the livelihoods that depend on a healthy and sustainable marine ecosystem.

Protecting menhaden benefits not only ospreys and other wildlife, but also the broader coastal ecosystem and the fishing communities that depend on it. Thank you.

Dear Members of the Atlantic Menhaden Management Board,

We are writing to express our strong support for a 50% reduction in the Chesapeake Bay reduction fishery cap (Option B4), lowering it from the current 51,000 metric tons to 25,500 metric tons, along with seasonal quota periods, as proposed in Draft Addendum II.

My wife and I are residents of Pasadena in Anne Arundel County, Maryland, and consider ourselves to be wildlife conservationists, avid boaters and concerned citizens who cares deeply about the health of the Chesapeake Bay.

We have lived at our current home, which situated on the northern shoreline of the Magothy River, for over 30 years. During that time the two of us, our children, and now our grandchildren, have come to love all the forms of recreation and wildlife the Bay has to offer. Each spring we eagerly await the return of the Osprey to signal that the end of winter is just around the corner. A few weeks later we watch as the females take to sitting on there nests and by May or June the little heads of their chicks begin to appear. We can see two of the nests from our home and frequently check on their status with our small spotting scope.

This year was so different, and not just a little bit different. Only one of the two pairs of Osprey behind our home returned. For the first time ever it produced no chicks. Same was true for the rest of the Magothy. In past years nearly all of the navigational buoys in the Magothy would have active Osprey nests - this year there was only a handful of nests and, as best as we can tell, none of them produced any chicks! Again, we are fairly active boaters, kayakers and birder watchers in and around the Magothy and surrounding waters and **WE SAW NO OSPREY CHICKS IN ANY NESTS THIS YEAR! NONE!**

The Bay is showing many signs of ecological stress. Declining productivity and widespread nest failures among ospreys is being reported by many experts. Those same experts report that this decline when combined with the stressed striped bass populations, point to a shortage of forage fish for the Bay's predators. Menhaden are a key link in that food web. These signals call for precautionary conservation now, not after further decline.
The concentration of the reduction fishery is also a serious concern. Industrial reduction fishing removes over 100 million pounds of fish within a concentrated summer window. That harms the local food web and deprives other user groups, including watermen, anglers, and coastal tourism economies, of fair access to the resource.

I therefore urge the Board to adopt strict seasonal quota periods that distribute harvest evenly across the year rather than allowing an intense summer harvest. Combined with the reduced cap, this would better protect the Bay's predators and the communities that depend on them.

Thank you for considering my comments and for your work to safeguard the Bay.

Respectfully,
Glenn & Theresa Reschke

I support the following selected alternatives for the Chesapeake Bay Cap, as ecologically and socioeconomically appropriate, to inform effective management actions, reduce the risk of overfishing, and promote resilient futures for the resource and its communities.

3.1 Chesapeake Bay Reduction Amount
: Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
: Option B1 – Even Length & Even Harvest.

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
: Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
: Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

The coastwide TAC must be reduced by at least 30%, from the current 186,840mt to 130,788 mt. Ideally, the coastwide TAC should be reduced by 50%, lowering the operating TAC to 94,420 mt. These are the only options to ensure the coastwide commercial Atlantic Menhaden fishery operates at a capacity that does not carry a 100% probability of overfishing.

Thank you,
Michael Asinas

Subject: [External] ASMFC-Chesapeake Bay Menhaden Reduction Fishery – Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

to: Atlantic States Marine Fisheries Commission – Atlantic Menhaden Management Board
Re: Chesapeake Bay Menhaden Reduction Fishery – Draft Addendum II

Dear Members of the Atlantic Menhaden Management Board:

I am writing as a Chesapeake Bay resident and professional naturalist /osprey scientist ,who cares deeply about the health of this Bay and the wildlife and communities that depend on it. I am asking you to reduce the Chesapeake Bay menhaden reduction-fishery cap by the maximum proposed 50% and spread distribution of the catch through the summer, 25, 25 and 50%(Option B2) reassess management every 3 years or sooner ,and to put the ecological needs of the Bay ahead of the continued expansion or concentration of industrial reduction fishing.

Menhaden are not simply another commercial fish. They are a foundation of the Chesapeake Bay food web. They provide food for striped bass and other fish, and they are particularly important to Chesapeake Bay ospreys.

The latest science should concern all of us. As a 43- year osprey research biologist surveying the Patuxent River, I participated in a study from 2024 - 2026 for the Center for Conservation Biology at Wm. and Mary, the study examined **almost 1000 osprey nests throughout the Chesapeake Bay** and we found substantial reproductive problems in higher-salinity areas. Compared with historical data from the 1980s, reproductive performance had declined at all high-salinity sites to all -time lows , worse by far than the peak of the DDT era 50 -70 years ago and the population is declining in the Bay by at least 14 % annually. An estimated more than 5000 chicks dying every year from starvation and lack of menhaden, formerly 75% of their diet but now less than 30%. The reproduction is at .**33 chicks per nest** , less than a third (**1.15 chicks**) needed to just remain a stable population. We as researchers found evidence of significant food stress and concluded that reduced availability of Atlantic menhaden may be a primary driver of poor osprey reproductive performance in those areas. **At this rate, the population of Ospreys within the Chesapeake is unsustainable.** Now this decline has spread to surrounding states as well. We believe Ospreys are the best bio -indicator species available for this topic and are sounding the alarm .

That finding deserves action—not dismissal.

I understand that the science does not establish that menhaden fishing is the only cause of osprey decline. Environmental conditions and other factors also affect osprey reproduction. In fact, CCB and USGS continues to investigate whether insufficient menhaden and other environmental factors are contributing to the problem. But uncertainty about every cause should not be used as a reason to continue removing large quantities of an important forage fish. When the health of an ecosystem is in question, precaution should guide management.

ASMFC itself recognized the problem when it established the Chesapeake Bay menhaden cap as a precautionary measure because of concerns about localized depletion. The current **51,000-metric-ton cap** was adopted in 2018, reflecting average reduction landings in the Bay during 2012–2016.

Now, in 2026, ASMFC is considering reducing that cap by as much as **50 percent**. The Commission says this review was prompted by declining pound-net harvest and catch rates in the Bay, increasing concentration of reduction harvest during the summer, and potential downstream effects on menhaden predators.

Those are not minor warning signs.

As a resident, I do not believe the Chesapeake Bay should be managed around the question of how many menhaden an industrial reduction fishery can legally remove. The question should be how many menhaden the Bay needs to remain a functioning ecosystem. Single species management won't work because it does not view the entire picture of the ecosystem, such as other contributing factors like predation needs (such as Osprey, Striped Bass, etc.) and environmental changes.

Omega Protein has a legitimate commercial interest in harvesting menhaden, but that commercial interest should not outweigh the public's interest in a healthy Chesapeake Bay. The menhaden in these waters belong to an ecosystem that supports ospreys, striped bass, other wildlife, recreational fishing, commercial fishing, tourism, and the communities surrounding the Bay.

I respectfully urge the Commission to:

• Reduce the Chesapeake Bay reduction-fishery cap substantially, at least 50% within the Bay and strongly consider reducing the Coastwide harvest to the maximum allowed.
• Prevent excessive concentration of harvest during the spring and summer;
• Strengthen monitoring of menhaden abundance and availability within the Bay;
• Continue to monitor results of independent research into osprey reproduction and menhaden availability; and
• Manage menhaden as an essential forage fish and ecosystem resource—not simply as an industrial commodity.

We should not wait until Chesapeake Bay ospreys, striped bass, and other menhaden dependent predators show unmistakable signs of ecosystem-wide food shortages before taking action. Be proactive. This is one thing we can control now.

I ask you to listen to the people who live beside this Bay, the scientists studying its wildlife, and the evidence showing that something has changed.

The Chesapeake Bay is a public resource. Its menhaden should first sustain the Bay's food web—not simply sustain an industrial harvest.

Please reduce the Chesapeake Bay menhaden reduction-fishery cap by 50% ,spread out the harvest 25,25 and 50% ,and adopt precautionary measures, such as reducing the Coastwide TAC , that ensures there are enough menhaden left in the water to support the Chesapeake Bay ecosystem.

Thank you for your consideration.

Respectfully ,

Greg Kearns , Professional naturalist and osprey scientist

Dunkirk , Md .

Subject: [External] Atlantic Menhaden - Support for Chesapeake Harvest Reduction!

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle:

We live on the MagothyRiver and have witnessed firsthand the decline in the river and bay fishes, all supported by significant data. **We strongly support a 50% reduction in the Chesapeake Bay fishery cap (Option B4/ reducing the cap to 25,500 metric tons) and support seasonal quota periods!**

Together with the stressed populations of striped bass, these declines signal an URGENT need for precautionary conservation practices NOW.
Industrial reduction fishing extracts over 100 million pounds of fish in a concentrated summer window, harming the local food web and depriving other groups, especially watermen and anglers, of fair access.
We urge fishery managers to implement strict quota periods that will distribute the harvest evenly across the year rather than allowing an intense summer harvest.

We live on the headwaters of the Chesapeake Bay's Magothy River, where it meets Cockey's Creek - brackish water. From our 100-year-old home's panoramic view we have watched what the data shows : critical decline in Osprey survival due to commercial overfishing.
Each year, 3 pairs of ospreys would arrive to build their nests in March , dive to catch adult-sized menhaden (not small fish) which were fed to the hatched chicks by the 4th of July. By Sept the young were leaving the nest & by October all departed and the Bald eagles & terns moved back in. Since the nests are built on all sorts of signs & poles, this was observable by boat all the way along the 5+mile long Magothy & creeks leading out to the bay.

Two years ago, there was a sudden & remarkable decline in nests containing any chicks. The osprey adults would dive, but come up empty, so unlike previous years! This year was far worse. The ospreys arrived & built nests, but by July there were NO chicks in any nest we passed by boat. The same decline in successful Osprey fishing 'dives' to sustain these large, well traveled birds seemed even worse. 2 of 'our' local 3 pairs LEFT in late July this year, as there appeared no reason to remain. More ominous, we could see dolphins & rays for the first time from our house. While at first this new development might seem exciting & delightful, instead it means that salt water species are starving enough to search fresh water creeks for food, where juvenile menhaden normally grow in their lifecycle from ocean to rivers & back to Chesapeake, normally achieving their 1-3 year adult size.

While it is fine to perform another study to confirm all the data that already exists, please do not wait to ban at least half of the currently allowed Menhaden harvest. Menhaden, we understand, also help

to filter the Chesapeake's water, also a topic of human concern.

Thank you for being a responsible steward of the entire Bay ecosystem before it is too late!

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Hi There,

I am writing because I'm concerned about the level of menhaden harvesting in the Chesapeake Bay. It has serious, problematic impacts on the entire east coast and our vital fisheries. Recreational and commercial fishermen are all suffering as a result, as are important marine species like whales, osprey, striped bass, and many others. I am urging you to please take serious action to limit menhaden harvests and protect the most vital marine ecosystems on the east coast, for the benefit of everyone who relies on the Atlantic Ocean.

Specifically, I strongly urge you to:
1. Reduce the Chesapeake Bay harvest cap by a full 50% as recommended by the latest scientific research.
2. Tie future caps to coastwide caps so that over time the Chesapeake harvest stays in step with other regions.
3. Distribute Chesapeake harvest seasons across the year so they don't only take fish in the spring and summer.
4. Reduce the coastwide menhaden harvest limit by at least 40%, also in keeping with the latest science.

You are the stewards of one of America's most vital and impactful fisheries. We are all relying on you as the only people who are in a position to preserve our fisheries for future generations. Please do what is right, without half measures, so that the Atlantic coast can continue to be the bountiful resource we all rely on.

Thanks,
Paul

Subject: [External] Atlantic Menhaden Draft Addendum II: CHESAPEAKE BAY CAP

Categories: Menhaden 2 Auto Replied

RE: Atlantic Menhaden Draft Addendum II**: Chesapeake Bay Cap**

My name is Andrew T. Manus. I am a retired conservation professional. Over my 40 year career, I have participated in the conservation field as the Executive Director of the University of Delaware Sea Grant College Program, the Director of the Delaware Division of Fish and Wildlife (in that capacity I served as an ASMFC Commissioner), the Mid-Atlantic Director of Conservation Programs for Ducks Unlimited and finished out my career as the Director of Conservation Program for The Nature Conservancy in Delaware. During the last eight years while retired I have chaired the Delaware Public Integrity Commission for three years and served as a Commissioner for five years.

I write to support the cutting of the current 51,000 metric-ton Bay Cap in half. This would leave 25,500 metric tons of additional menhaden in the Bay. The basis for my support is both ecological and ethically driven. Menhaden are a vital forage fish. They nourish larger predators like striped bass, osprey, whales, dolphins and pelicans. Removing menhaden at the current rates is having a deleterious effect on the ocean and estuarine ecosystems and causing decline across multiple species noted above.

Modern industrial menhaden fishing uses massive purse seines and spotter planes to clear enormous volumes of fish from nearshore nurseries like the Chesapeake Bay. I believe that my support for the reduction noted above is a more ethical and responsible approach to the harvesting of menhaden than the current industrial dominated one currently in place. The menhaden fishery is a natural resource that belongs to all the people and future generations, not just the current commercial enterprises.

In closing, I request the ASMFC factor into its decision making future generations intrinsic right to experience vibrant, living estuaries and abundant coastal life, rather than inheriting a

depleted ecosystem. For menhaden to be a healthy fishery it must move beyond being simply viewed as a commodity that generates corporate earnings or tons of fishmeal produced.

I live on the long island sound. Prior to the past three summers we would have schools of bunker swimming around the Sound. Yet more recently, I have yet to see any schools. I am not a fisherman but I do worry about the local wildlife that is dependent on the bunker such as the Osprey. Hopefully you can do something to reduce the overfishing and improve our local ecosystem. thanks, Matt Barkoff

To whom it may concern,

I support the strongest proposed conservation measures, which are the following:

- 3.1 Chesapeake Bay Reduction Fishery Cap Amount - **Option C1e: that reduces the CAP by at least 50 percent in 2027 (25,500 mt) and limits the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).**
- 3.2 Chesapeake Bay Cap Distribution - **Option B2, which establishes three even length quota periods for the Bay Cap, but distributes harvest 25% in period 1, 25% in period 2, and 50% into period 3.**
- 3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision - **Option B to revisit the Bay Cap every 3 years.**

Our family has been boating and living along the Chesapeake Bay for more than 20 years and we have a deep connection to the waters and ecosystems of this area. As the largest estuary in the United States, the Chesapeake Bay is a critical breeding and nesting ground for many land and water species along the entire eastern seaboard. While I understand there are many environmental stressors the Bay must endure, the massive harvests of menhaden is a contributing factor to the decline in critical species such as the osprey and striped bass.

We have an osprey nest at the end of our dock and this summer was the first time in more than ten years the osprey offspring did not survive. While this is anecdotal, it is consistent with broader data which shows widespread osprey productivity declines. I believe it is in part due to a lack of small menhaden in the late spring when they are needed by the osprey to feed their hatchlings. The osprey are starving. In the late spring/early summer, we used to see large schools of menhaden in the waters off our dock, but this year they did not come until late in the summer, after the osprey chick(s) had died.

These declines signal an URGENT need for precautionary conservation practices. Industrial reduction fishing extracts over 100 million pounds of fish in a concentrated summer window, harming the local food web and depriving other groups, especially watermen and anglers, of fair access. We urge fishery managers to implement strict quota periods that will distribute the harvest evenly across the year rather than allowing an intense summer harvest.

While I agree with the need for a broader study that has been funded by the state of Virginia, we cannot wait for the results to take action. We must limit the menhaden harvesting as much as possible NOW and once the results of the study are available, a more permanent plan can be determined.

Thank you for taking public comments and considering the interests of all who care about the Bay. Please take action to limit industrial fishing until we know more.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

I support the following selected alternatives for the Chesapeake Bay Cap, as ecologically and socioeconomically appropriate, to inform effective management actions, reduce the risk of overfishing, and promote resilient futures for the resource and its communities.

3.1 Chesapeake Bay Reduction Amount
: Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
: Option B1 – Even Length & Even Harvest.

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
: Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
: Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

The coastwide TAC must be reduced by at least 30%, from the current 186,840mt to 130,788 mt. Ideally, the coastwide TAC should be reduced by 50%, lowering the operating TAC to 94,420 mt. These are the only options to ensure the coastwide commercial Atlantic Menhaden fishery operates at a capacity that does not carry a 100% probability of overfishing.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic Menhaden Management Board,

My name is Charles Post. I am a UC Berkeley-trained ecologist, conservation filmmaker, and lifelong birder who grew up watching ospreys hunt menhaden on Cape Cod. Those experiences helped shape my understanding of how deeply connected our coastal ecosystems are, and why protecting the fish that sustain them matters.

I am writing in support of a 50% reduction in the Chesapeake Bay reduction fishery cap under Draft Addendum II. I also support seasonal quota periods that limit concentrated harvest during spring and summer, when breeding birds and other predators depend on reliable access to forage fish.

As an ecologist, I believe management must account for where and when prey is available, alongside the overall abundance of a fish population. An osprey raising chicks needs fish within reach of its nest. Coastwide abundance alone cannot tell us whether that bird has enough food.

I urge the Board to take a precautionary approach that leaves more menhaden in the water while supporting continued research into local prey availability and predator needs. Scientific uncertainty should motivate careful management and better monitoring, rather than delay meaningful protection.

I recognize that these decisions affect fishing livelihoods. Protecting the ecological foundation of our coastal waters is also an investment in the communities, fisheries, and wildlife that depend on them.

Watching an osprey emerge from the water with a menhaden remains one of the most memorable sights of my childhood. I want future generations to experience that same sense of wonder along a coast that continues to support abundant life.

Thank you for considering my comments and for your work on behalf of our shared coastal resources.

Sincerely,
Charles Post

Dear Atlantic State MarineFisheries Commission,

Please pass tighter limits on menhaden harvests in the Chesapeake Bay and beyond. Overfishing has caused the number of successful osprey hatchlings to plummet in the past year.

Such a drastic decline does not bode well for marine ecosystem health.

I hope you will do the right thing.

Thank you.

Sincerely,

Patsy Wang-Iverson

Subject: [External] Atlantic Menhaden Draft Addendum II Testimony

Categories: Menhaden 2 Auto Replied

To the Atlantic States Marine Fishing Commission,

My interest in Atlantic Menhaden Draft Addendum is both personal and longstanding. I live along the Connecticut shore and have been a Connecticut Audubon Society osprey monitor for 13 years. I am also the administrator of the Osprey Stewards East Coast Alliance, an independent coalition of osprey monitors in the Atlantic states concerned about osprey decline.

In 2025 Connecticut monitoring data revealed the first decline in osprey fledgling production in more than 15 years at a rate of 1.26 chicks per pair. Reports from the 2026 Connecticut nesting season are even more alarming with a rate of 0.87 chicks per pair and a 40% nesting failure.

Adult ospreys are increasingly unable to locate sufficient menhaden resulting in starving chicks, nest failures, abandoned nests and chick and fledgling deaths. Similar devastating, unsustainable declines are being observed up and down the Atlantic Coast.

Nutrient-rich menhaden serve as the foundational food source of ospreys constituting roughly three-quarters or more of their total prey. This extreme osprey food stress has been documented in recent years to be caused by a decreased availability of Atlantic menhaden to nesting ospreys due to industrial-scale harvesting in the Chesapeake Bay.

Rebuilding menhaden populations is one of the fastest and most effective actions that can be taken to maintain a balanced and productive marine ecosystem and to restore osprey populations,

It's time to act. I strongly support the most protective alternatives available under Draft Addendum II, and I respectfully ask you to demonstrate your conservation leadership by imposing the maximum 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons.

I also support measures that reduce concentrated harvest during ecologically important periods and prevent future increases in the coastwide TAC from automatically increasing industrial fishing pressure within Chesapeake Bay. and spreading the harvest more evenly across the season and linking the Chesapeake cap to the Atlantic coast's total allowable catch.

In addition, Chesapeake-specific research should be accelerated, and all these measures should be treated as an interim step toward ultimately moving the industrial reduction fishery out of Virginia state waters.

It is up to politicians, regulators, managers (like the ASMFC) to listen—and act—before it is too late.

Thank you for your leadership and commitment to science-based fisheries management. I respectfully urge you to take the next critical steps by protecting menhaden so that both wildlife and coastal communities ana a healthy ecosystem can thrive.

For the osprey,

Subject: [External] Plummeting Osprey Population

Categories: Menhaden 2 Auto Replied

Dear Commissioners,

I am writing because I am deeply alarmed by the decline in the coastal osprey population and the potential consequences for these important coastal ecosystems.

Ospreys are highly dependent on menhaden as a food source, and I am concerned that continued pressure from menhaden harvesting could further limit the availability of this critical forage fish. Protecting healthy menhaden populations is not only important for ospreys, but for the broader coastal food web and the many species that depend on them.

I urge the Commission to take a precautionary approach and drastically reduce the allowable menhaden harvest. Given the apparent decline in coastal osprey populations, I believe stronger protections are warranted to ensure that sufficient menhaden remain available to support ospreys and other predators.

I respectfully ask the Commission to consider the ecological needs of ospreys and the broader coastal ecosystem when setting menhaden harvest limits, and to prioritize the long-term health of these populations over maximizing short-term harvest.

Thank you for your consideration and for your work to protect our coastal resources. I hope you will take meaningful action to ensure that menhaden remain abundant enough to sustain the wildlife that depends on them.

Sincerely,

Amy Bryan

As a resident of Deltaville, Virginia for many decades and a lifelong Chesapeake Bay boater and angler, I have personally experienced the decline of the sportfishing industry and its dramatic impact on the economic viability of small waterfront towns like Deltaville. I support the conservation options in Draft Addendum II. I urge the Board to cut the Chesapeake Bay reduction-fishery cap — fixing it at
25,500 metric tons, as the American Saltwater Guides Association recommends — and to adopt quota periods that spread harvest across the season, so menhaden remain available to striped bass, ospreys, and the rest of the Bay food web through the critical summer months. I also support the proposed 40% cut to the coastwide total allowable catch for 2027–28. Please hold to the Commission's ecosystem-based management objectives.

Thank you for the opportunity to comment.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic Menhaden Management Board,

I am writing as an active Chesapeake Bay boater, recreational angler, and coastal resident to express my strong support for aggressive, precautionary management under Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden.

Atlantic menhaden serve as the ecological keystone of the Chesapeake Bay estuary. They are the primary forage base supporting striped bass, bluefish, weakfish, marine mammals, and breeding ospreys. While coastwide stocks outside the Bay may demonstrate stability, localized depletion inside the Chesapeake nursery waters remains an urgent crisis that directly threatens recreational fisheries and avian survival.
I urge the Board to adopt the following specific management options:

* Issue 1 – Chesapeake Bay Reduction Fishery Cap: Support Option C1e. The Bay Cap must be directly tied to the total commercial coastwide TAC at a reduced rate of 13.6% (resulting in an initial cap of 25,500 metric tons). This 50% reduction to the Bay cap is an essential, long-overdue step to prevent localized overharvest and push industrial reduction purse-seining out into open federal waters.

* Issue 2 – Quota Timing within the Chesapeake Bay Cap: Support Option B2 (Seasonal Harvest Distribution: 25% / 25% / 50%). Splitting the cap into distinct seasonal windows ensures that the reduction fleet cannot aggressively harvest large schools during peak warm-weather months, leaving vital forage in place during critical feeding and nesting periods for striped bass and ospreys.

* Issue 3 – Bay Cap Review Provision: Support Option B (3-Year Revisit). The Board must formally revisit and evaluate the Bay Cap every three years as new ecological and localized depletion science becomes available.
Thank you for your dedication to science-based, ecosystem-level management of our shared marine resources. Please protect the ecological foundation of the Chesapeake Bay.

Sincerely,
Patricia Creveling

Subject: [External] Menhaden catch limit

Categories: Menhaden 2 Auto Replied

Good evening.

I am writing to encourage ASMFC to tighten limits on menhaden harvests in the Chesapeake Bay and beyond, including along the Jersey coast.

One need not be a scientist to appreciate the importance of balance and of our complex environmental chains. Every component, every link, plays a role. When that link is gone, the chains, e.g., food chain, are broken, additional links are lost, and our environmental system goes out of balance. The system will find a new equilibrium point, eventually, but that balancing process can be long and painful.

Menhaden is one link. I am asking you to respect each link's vital importance. Please protect menhaden and osprey, which depend on them for food.

Sincerely,
Stanley Goodman
Wyckoff, NJ

Subject: [External] Approve Draft Addendum II - Support science-based menhaden management

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator Boyle,

As a recreational angler, I urge the Atlantic States Marine Fisheries Commission to approve Draft Addendum II and reform menhaden management to better support the entire Chesapeake Bay ecosystem and recreational fishing.

Menhaden are critical forage for striped bass, bluefish, red drum, cobia and other sportfish. They are also one of the Atlantic Coastb□s most important recreational baits. Maintaining a healthy and abundant menhaden population is essential to the health of these fisheries and the coastal communities and businesses that depend on them. The economic importance of menhaden to recreational fishing is also significant. According to a new study by Southwick Associates, anglers used menhaden on an estimated 13.9 million fishing days in 2025, generating approximately $804 million in spending and supporting more than 7,200 jobs. This included 6.3 million fishing days in the Mid-Atlantic, 5.1 million in the South Atlantic and 2.5 million in New England.

I respectfully ask the Board to approve the following measures in Draft Addendum II:

-Options C1e and C2a, which would link the Chesapeake Bay Reduction Fishery Cap to approximately 13.6% of the coastwide total allowable catch while retaining the existing 51,000-metric-ton upper limit. At the current coastwide quota, this would reduce the Bay Cap by approximately 50%, to 25,500 metric tons.
-Option B2, which would distribute harvest across 25% / 25% / 50% seasonal quota periods and reduce the potential for concentrated fishing when forage may be especially important to predators.
-Option B, which would deduct early-period overages from the following quota period while allowing unused quota to roll forward.

A requirement to revisit the Bay Cap every three years so managers can incorporate new Chesapeake Bay-specific science and respond to our evolving understanding of menhaden and predator needs.

I also support setting the 2027b□2028 coastwide total allowable catch at a level carrying no more than a 50% probability of exceeding the Ecological Reference Point fishing mortality target. Managing menhaden to the ERP fishing mortality target achieves both ecological and economic goals by protecting the role of menhaden in the ecosystem while providing for the livelihoods of bait fishermen, tackle shop owners, guides, and all others who rely on menhaden to support recreational fisheries.

Please approve Draft Addendum II and take meaningful action to ensure that menhaden management supports a healthy Chesapeake Bay, abundant sportfish populations and sustainable recreational fishing opportunities.

Sincerely,

Michael LaRaia

Commercial allowable catch limits for Atlantic menhaden should be reduced because menhaden serve as a critical foundation for the entire marine ecosystem. They are a primary food source for economically vital sportfish (like striped bass, bluefish, and weakfish), marine mammals, and seabirds (such as ospreys and eagles). The dolphin and whales and seals and all marine life need the abundance to survive and we can tell by spending a lot of time on the water that menhaden numbers are drastically down. Leaving more menhaden in the water directly supports the recovery and stabilization of these predator populations, which are currently facing severe pressures.

Subject: [External] Protect Menhaden; protect our coastal wildlife

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission,

Our coastal and Meadowlands ecosystems are suffering, and birds and fish are struggling to find the food they need to survive. The depletion of menhaden—a critical food source for countless marine and coastal species—is putting tremendous pressure on this fragile ecosystem. The impact is especially concerning among our protected osprey population, which depends heavily on menhaden for survival.

We must strengthen restrictions on industrial menhaden fishing before further damage is done. Allowing large-scale harvesting to continue at the expense of our wildlife and natural habitats is environmentally irresponsible and unsustainable.

Please take meaningful action to protect menhaden from overfishing, rebuild their populations, and restore this essential food source. The health of our coastal waters, the Meadowlands, and the wildlife that depend on them is at stake. Protecting menhaden means protecting the entire ecosystem. You can reverse this damage! Please, please, do so!

Very Concerned,

Nancy Dhulipala

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

To the ASMFC Commissioners,

I have volunteered as a docent for a local nature center in Connecticut for the past four years, during which time I have closely monitored several osprey nests in the state park. Through monitoring of the ospreys, I noticed that this past season showed a dramatic change in nests. Nests that previously had multiple fledglings struggled this year to bring even 1 of their eggs to the end of the season. While watching the live feed from the nest outside the nature center each Sunday for hours, I observed a drastic decrease in the number of fish brought in this year and their size was noticeably smaller.

This anecdotal evidence is consistent with the Connecticut Audubon Society's preliminary report: with 99% of the season's data compiled, osprey productivity stood at 0.87 chicks per breeding pair. This is down sharply from the previous record low of 1.26 in 2025.

In Rhode Island, only 38% of 339 monitored nests successfully fledged young. That's only 0.33 young per pair.

In 2025, Conserve Wildlife Foundation of New Jersey documented the worst breeding season in more than 30 years. For osprey to maintain a stable population, the required number is 0.8 young per pair.

The Connecticut Audubon Society along with Oceana, The American Bird Conservancy, The National Wildlife Federation Action Fund, Conserve Wildlife Foundation of New Jersey, New Jersey Osprey Project. and others are stating osprey populations are in trouble This has been documented in recent years to be caused by a decreased availability of Atlantic menhaden to nesting ospreys due to industrial-scale harvesting in the Chesapeake Bay. Menhaden constituting three-quarters or more of the osprey's total prey especially when the chicks are young.

Adult ospreys are increasingly unable to locate sufficient menhaden resulting in starving chicks, nest failures, abandoned nests and chick and fledgling deaths.

It's time to act. I respectfully ask you to pause altogether or significantly reduce the Chesapeake Bay menhaden catch by 50%, spread the harvest more evenly across the season, and link the Chesapeake Bay cap to the Atlantic coast's total allowable catch.

Restoring menhaden populations is one of the most effective ways to maintain a balanced and productive marine ecosystem and to restore osprey populations.

Please take the next critical step by protecting menhaden so that both wildlife and a healthy ecosystem can thrive.

Sincerely,
Christine Bastien-Williams

My name is Alexander Mayer and I fish out of Montauk, New York.
Striped bass, bluefish, and tuna — the species that sustain our local fishing — depend on menhaden as forage, and I have watched the inshore forage base thin out year after year. I support Addendum II's option to cut the Chesapeake Bay reduction-fishery cap and to spread that harvest across the season, and I support setting a conservative coastwide TAC for 2027–2028 rather than maximizing industrial removal of the coast's primary forage fish. I have separately asked my congressional delegation and the Governor of New York to press the Secretary of Commerce to initiate rulemaking for a 12-nautical-mile year-round buffer against the reduction fleet along the Atlantic coast. Please act now, while the stock can still support both the fishery and everything that eats menhaden.

Subject: [External] Limits on menhaden fishing

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission,

I am writing to express my serious concern about the dramatic decline in coastal osprey populations and to urge the Commission to take stronger action to protect Atlantic menhaden.
Menhaden are not simply another commercial fishery. They are a critical forage species that supports ospreys and many other predators throughout the Atlantic coastal ecosystem. When menhaden become scarce in areas where ospreys feed, the consequences can extend throughout the food web and can be particularly damaging during the nesting season, when adult birds must find sufficient food for their young.

The continued decline of coastal ospreys should be treated as an important warning sign. Fisheries management should account not only for the sustainability of the harvested species itself, but also for the needs of the wildlife and ecosystems that depend upon it.
I urge the ASMFC to substantially reduce the allowable menhaden harvest, particularly in ecologically sensitive coastal areas, and adopt management policies that explicitly account for the forage needs of ospreys and other predators.

We should not wait until these populations reach a crisis point before taking meaningful action. A healthy menhaden population is essential to a healthy Atlantic coastal ecosystem.
Thank you for considering these concerns and for your stewardship of our marine resources.

Sincerely,
Kathleen Shaw

Leesburg, NJ

Dear Mr. Boyle and the Atlantic Menhaden Management Board and others:

I am writing as a concerned NJ citizen, a Citizen Scientist, a past NJ Bald Eagle Nest Observer for NJ Conserve Wildlife, a retired NJ public school educator (Aquaculture), a retired NJ Apprentice Wildlife Rehabilitator, an avid bird-watcher, and a grandmother to six young New Jersey citizens (whom I hope will get to see the full spectrum of NJ wildlife in their lifetime, to urge the Atlantic States Marine Fisheries Commission (ASMFC) to adopt strong, precautionary management measures within **Draft Addendum II**. Atlantic menhaden are the backbone of our coastal waters, serving as a critical forage fish for ospreys, whales, striped bass, and countless other marine species. They are the critical link in the sea's food chain.

I would ask for a **total moratorium on menhaden fishing**, until their populations become stable.

Some points I would like your to consider:

- FISHERIES CONSERVATION protects and restores fish stocks and aquatic habitats to ensure long-term marine and freshwater health.

- The restrictions put in place in 2012 worked! Please make that happen again.

- You say the menhaden are not overfished, but we all heard one commenter after another at the public hearings, and many other venues, that menhaden have all but disappeared along the eastern seaboard.

- There are more stakeholders in menhaden than just Omega Protein. You and the Board must see that.

- Yes, jobs in Virginia will be lost. If the menhaden harvest dries up, they will be lost anyway. Omega Protein can resolve to change. They can adapt and make oil from algae and fish-trimming and maintain the jobs in Virginia.

- 92 percent of Virginia Voters Want to Leave More Menhaden in the Chesapeake Bay (https://www.cbf.org/wp-content/uploads/2025/10/va-menhaden-survey-2025.pdf)

- Don't make this political!

I would remind you of your mission:

ASMFC's mission:

> **"Our Mission**
>
> To promote cooperative management of fisheries — marine, shell, and diadromous — of the Atlantic coast of the United States by the protection and enhancement of such fisheries, and by the avoidance of physical waste of the fisheries from any cause…" (https://asmfc.org/about/)

and

ASMFC's reason for being:

"ASMFC Overview The Commission was formed by the 15 Atlantic coastal states in 1942. The states formed the Commission to assist in managing and conserving their shared coastal resources. The states recognize that they cannot protect their citizen's interest in the resource alone. Because marine fish species move among many states, sometimes over wide ranges, each state knows it needs the cooperation of the other states in order to be successful. The Commission is nothing more, nothing less, than the place where the states come together to define what needs to be done to accomplish their mutual interests towards common goals; and to abide by majority rule in order to work together to pursue the goals. (Pg 1) *ASMFC Advisory Primer: A Guide to the Commission's Advisory Panel Process.*

Within the limitations of your survey, which I filled out on your site; I urge the Board to implement the following recommendations, I am taking advisement on my decisions from

American Littoral Society and multiple other organizations that I align with, trust, and respect:

- **Reduce the Chesapeake Bay Industrial Harvest Cap by at least 50%:** Cutting the current cap will safeguard the Bay's role as an indispensable nursery ground for juvenile menhaden, which ultimately migrate to support ecosystems along the entire Atlantic coast.
- **Establish Seasonal Quota Periods:** Spreading the allowed catch more evenly across the fishing season will prevent concentrated depletion and reduce localized ecological crises during critical wildlife feeding windows.
- **Mandate a Triennial Cap Review:** Ensure that the Bay cap is reassessed at least once every three years to integrate the latest ecological data and respond to evolving localized ecosystem needs.
- **Maintain an Independent Cap Structure:** Keep the Chesapeake Bay harvest limit independent, preventing it from being automatically tied to or inflated by changes in the broader coastwide quota.
- **Adopt Substantial Coastwide Catch Reductions:** Set 2027–2029 specifications that align directly with the ASMFC's ecosystem-based management targets, keeping more menhaden in the water to guarantee a resilient, thriving coastal food web.

One more thing I would like to share with you, a beautifully written excerpt from *The Most Important Fish in the Sea*, by H. Bruce Franklin. Hopefully, this book is NOT unfamiliar to you all, and will remind you of the bigger picture:

Franklin writes,

"First you see the birds- gulls and terns wheeling overhead, then swooping down to a wide expanse of water dimpled as though by large raindrops and glittering with silver streaks. The sea erupts with frothy splashes, some from the diving birds, others from foot-long fish with deeply forked tails frantically hurling themselves out of the water, only to fall back into their tightly packed school. More and more birds materialize as if from nowhere, and the air rings with their shrill screams. Boats too begin to converge on the scene: the boiling cloud of birds has told anglers everywhere within view that a school of menhaden, perhaps numbering in the tens of thousands, is being ravaged by a school of bluefish.

Attacking from below and behind to slash the menhaden bodies with their powerful jaws, the razor-toothed blues are in a killing frenzy, gorging themselves with the severed backs and bellies of their prey some killing even when they are too full to eat, some vomiting half

digested pieces so they can kill and eat again. Terns skim gracefully over the surface with their pointed bills down, dipping to pluck bits of flesh and entrails from the bloody swirls. Gulls plummet and fop heavily into the water, where a few splash about and squabble noisily over larger morsels. As some lift with their prizes, the squabbles turn aerial and a piece occasionally falls back into the water, starting a new round of shrieking skirmishes. Hovering high above the other birds, a male osprey scans for targets beneath the surface, then suddenly folds its gull-shaped wings and power-dives through the aerial tumult, extends its legs and raises its wings high over its head an instant before knifing into the water in a plume of spray, emerges in another plume and laboriously flaps its four-foot wingspan as it slowly climbs and soars away with a writhing menhaden held headfirst in its talons. Beneath the blues, iridescent weakfish begin to circle, snapping at small lumps sinking from the carnage. Farther below, giant but toothless striped bass gobble tumbling heads and other chunks too big for the mouths of the weakfish. From time to time, bass muscle their way up through the blues, swallow whole menhaden alive, and propel themselves back down with their broom-like tails, leaving telltale swirls on the surface. On the mud below, crabs scuttle to scavenge on leftovers" (pgs. 3-4).

Thank you for your dedication to science-based, ecosystem-first fisheries management.

Sincerely,

Elizabeth Thompson

Subject: Public Comment: Atlantic Menhaden Management – Urgent Request for 50% Chesapeake Bay Cap Reduction and Catch Reallocation

Dear Atlantic States Marine Fisheries Commission (ASMFC) Menhaden Management Board,

I am writing to submit formal public comment as an **osprey biologist actively monitoring avian populations along the Patuxent River in Maryland**. Based on critical ecological field evidence and reproductive studies, I urgently request that the Commission implement the **maximum reduction of 50% to the commercial harvest cap within the Chesapeake Bay** and dynamically restructure the broader catch limits to a **25%, 25%, and 50% allocation framework**.

Our monitoring data along **the Patuxent River ecosystem for over 40 years** continues to document an unprecedented and accelerating collapse in osprey nesting success and chick survival. (see tables below)This reproductive failure is driven entirely by starvation due to the acute, localized depletion of Atlantic menhaden—the primary lipid-rich forage base required to sustain breeding Ospreys.

This localized forage crisis is heavily detailed in the comprehensive, long-term Osprey research led by Dr .Bryan Watts in a major collaborative study with the **College of William & Mary**. This landmark research provides undeniable empirical evidence that heavy commercial reduction fishing inside the Bay ecosystem leaves parent ospreys unable to provision their young. The result is widespread brood reduction and historic lows in fledgling success. **1.15** chicks per nest is needed to remain stable and now down to .**46** chicks in the Patuxent study area shown below, well under maintenance level .

To halt this ecological collapse and honor true ecosystem-based fisheries management, I ask the ASMFC to adopt the following two structural management updates .

- **Enact a 50% Reduction in the Chesapeake Bay Cap and lower the TAC in the Atlantic :** Immediately slash the localized commercial reduction harvest cap within the Bay by the maximum 50% allowance to preserve immediate forage biomass for nesting bird predators and fish predators, as well as whales and dolphins . Caution should be exercised until menhaden population studies are completed in the Chesapeake Bay by Maryland and Virginia , not wait until they are completed and continue massive reduction fishing by Omega Protein in the meantime with business as usual to Omega's benefit of a public resource . The population should be known before any further harvests allowed to prevent a potential colipase of the ecosystem and Ospreys ,which are already past a tipping point by our research and observations. Why wait until it's too late like other fisheries that have collapsed in America , almost suddenly after intense fishing pressure ? Then a difficult recovery period if even possible . Lessons should be learned from the past mistakes when ASMFC biologists admit they have grossly overestimated the menhaden population. Observations by public and professionals agree menhaden are much harder to find , especially larger adults that contain the high level fatty acids and calories needed by ospreys in the Bay.
- **Reallocate the Catch Limits to 25%, 25%, and 50%:** Distribute the coastwide catch limits under a balanced tier system (25% commercial reduction, 25% bait fishery, and 50% ecological

conservation buffer) to guarantee that upper-trophic level predators are legally insulated from systemic food scarcity.

Managing menhaden as an isolated commercial commodity is actively destroying the biological integrity of the Chesapeake Bay nursery and tributaries. The ASMFC must take immediate action to prioritize the forage demands of our coastal ecosystems.

Thank you for your time and serious consideration of these emergency targets.

Sincerely,

Greg Kearns

Subject: [External] atlantin menhaden 2027-2028 TAC

Categories: Menhaden 2 Auto Replied

We need the coastwide TAC immediately cut by at least 40% to 112,000 MT OR MORE.
Set the TAC as fixed tonnage for 27 and 28
DONOT link the bay cap to the coastwide TAC Bay cap should remain separate.
Although a reach and not on the table of options currently, I support visiting the possible full closure of Atlantic menhaden harvest until a time we can restore their numbers
Our coastline is dying and menhaden play a key role in a healthy ecosystem and sustaining everything that eats them along out coast. Omega proteins' profits as well as other net boats should not be considered more important than the greater good and value of these fish alive and well in our ecosystem. As it stands, our oceans are hanging on by a thread. Barely alive compared to what they once were.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Hello,

I urge the Atlantic States Marine Fisheries Commission to adopt the strongest scientifically supported conservation measures under Atlantic Menhaden Draft Addendum II, including a 50% reduction in the Chesapeake Bay reduction fishery cap, along with measures to distribute harvesting more evenly throughout the fishing season.

Atlantic menhaden are not simply a commodity for commercial reduction fisheries. They are a critical forage fish that supports marine food webs and provides essential nutrition to numerous predators, including ospreys, striped bass, and other fish-eating wildlife. Removing large quantities of these fish from the ecosystem can reduce food availability for predators and disrupt the ecological balance of Chesapeake Bay.

I am deeply concerned about managing wildlife and natural resources primarily for commercial extraction while failing to adequately protect the broader ecosystem. Healthy ecosystems depend on maintaining sufficient prey populations to support the wildlife that relies on them. Fisheries management must consider these interconnected relationships rather than focusing narrowly on harvest levels and commercial interests.

I urge the Commission to:

Adopt a 50% reduction in the Chesapeake Bay reduction fishery cap as a precautionary measure to reduce fishing pressure.
Establish quota periods that prevent concentrated harvesting during critical seasons when predators depend on menhaden for food.
Use an ecosystem-based management approach that accounts for the dietary needs of predators and the ecological importance of menhaden.
Require ongoing scientific monitoring of menhaden abundance, availability, and the effects of commercial harvesting on dependent wildlife.
Apply precautionary management when significant scientific uncertainties remain, rather than waiting for clear evidence of ecological damage before acting.
Prioritize long-term ecosystem health and biodiversity over maximizing commercial extraction.

The Commission’s own review process has recognized concerns about concentrated fishing effort, potential ecological impacts, and the need for precautionary management. These concerns warrant meaningful action, not simply maintaining the status quo.

As someone who cares deeply about wildlife conservation and biodiversity, I believe that protecting the natural systems that sustain wildlife must be a fundamental priority. We cannot continue removing essential resources from ecosystems without adequately accounting for the consequences for the species that depend on them.

Please adopt the strongest effective conservation measures in Draft Addendum II and ensure that Atlantic menhaden management prioritizes ecosystem health, biodiversity, and the long-term sustainability of marine wildlife.

Thank you,

Shari Dalal

Subject: [External] Please Help Protect Our Chesapeake Bay Osprey

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

I am writing to express my support for the strongest possible reduction in the Chesapeake Bay menhaden catch cap and the implementation of seasonal quota periods under Draft Addendum II.

The Chesapeake Bay is a special part of our lives here in Southern Maryland. My family and I look forward to seeing osprey return to our shores every spring, and it is heartbreaking to learn that these magnificent birds are struggling to find enough food to feed their young.

Menhaden are a critical food source for osprey and other wildlife, including striped bass. I believe protecting this important resource is essential to maintaining a healthy Chesapeake Bay and ensuring future generations can enjoy the wildlife that makes this area so special.

I urge you to adopt the strongest available protections to help restore the osprey population and preserve the Bay's ecosystem. We have an opportunity to make a meaningful difference, and I hope you will take action before more nests are left empty.

Thank you for considering my comments and for your work to protect our shared natural resources.

Sincerely,

Haley Hoyt

Subject: [External] Atlantic Menhaden Draft Amendment II

Categories: Menhaden 2 Auto Replied

I am in support of the amendment to reduce the catch limit of Menhaden fish in order to save the osprey population that is collapsing. I also support the quotas to limit the summer harvest and evenly distribute the catch limits throughout the year to ensure that these important fish are not severely depleted--which threatens the osprey population and also the stripped bass.

I live in Calvert County, Maryland and I see the drastic reduction of the osprey and also the stripped bass in the Chesapeake Bay.

Sincerely,

John J Stueckler

Subject: [External] Approve Draft Addendum II - Support science-based menhaden management

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator Boyle,

As a recreational angler, I urge the Atlantic States Marine Fisheries Commission to approve Draft Addendum II and reform menhaden management to better support the entire Chesapeake Bay ecosystem and recreational fishing.

Menhaden are critical forage for striped bass, bluefish, red drum, cobia and other sportfish. They are also one of the Atlantic Coastb□s most important recreational baits. Maintaining a healthy and abundant menhaden population is essential to the health of these fisheries and the coastal communities and businesses that depend on them. The economic importance of menhaden to recreational fishing is also significant. According to a new study by Southwick Associates, anglers used menhaden on an estimated 13.9 million fishing days in 2025, generating approximately $804 million in spending and supporting more than 7,200 jobs. This included 6.3 million fishing days in the Mid-Atlantic, 5.1 million in the South Atlantic and 2.5 million in New England.

I respectfully ask the Board to approve the following measures in Draft Addendum II:

-Options C1e and C2a, which would link the Chesapeake Bay Reduction Fishery Cap to approximately 13.6% of the coastwide total allowable catch while retaining the existing 51,000-metric-ton upper limit. At the current coastwide quota, this would reduce the Bay Cap by approximately 50%, to 25,500 metric tons.
-Option B2, which would distribute harvest across 25% / 25% / 50% seasonal quota periods and reduce the potential for concentrated fishing when forage may be especially important to predators.
-Option B, which would deduct early-period overages from the following quota period while allowing unused quota to roll forward.

A requirement to revisit the Bay Cap every three years so managers can incorporate new Chesapeake Bay-specific science and respond to our evolving understanding of menhaden and predator needs.

I also support setting the 2027b□2028 coastwide total allowable catch at a level carrying no more than a 50% probability of exceeding the Ecological Reference Point fishing mortality target. Managing menhaden to the ERP fishing mortality target achieves both ecological and economic goals by protecting the role of menhaden in the ecosystem while providing for the livelihoods of bait fishermen, tackle shop owners, guides, and all others who rely on menhaden to support recreational fisheries.

Please approve Draft Addendum II and take meaningful action to ensure that menhaden management supports a healthy Chesapeake Bay, abundant sportfish populations and sustainable recreational fishing opportunities.

Sincerely,

Ryan Wimer
35 Liberty Ln

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

SUBJECT: Public Comment: Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden

TO: Atlantic States Marine Fisheries Commission (ASMFC)

SUBMITTED VIA: comments@asmfc.org / ASMFC Public Comment Survey

The Atlantic States Marine Fisheries Commission (ASMFC) must immediately enforce the maximum precautionary safeguards proposed under Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden. Industrial-scale reduction fishing in the primary nursery waters of the Chesapeake Bay presents an immediate ecological hazard to marine food webs and avian species. The Commission must prioritize public trust resources and ecosystem health over commercial reduction exploitation.

1. Mandate Option B4: The Full 50% Cut to the Chesapeake Bay Reduction Cap

The ASMFC must select Option B4 to reduce the Chesapeake Bay Reduction Fishery Cap by the full 50% (capping Bay reduction landings at 25,500 metric tons). Concentrated purse-seining by massive fleet operations strips vital forage from localized waters. The historical Bay Cap was established based on commercial landings rather than ecological science; a 50% cut is mandatory to relieve localized depletion and safeguard estuarine nursery functions.

2. Establish Three Seasonal Quota Periods and Prohibit Underage Rollovers

The Commission must divide the Bay Cap into three distinct seasonal quota periods to prevent industrial fleets from concentrating harvest during critical spring and summer wildlife breeding cycles. Furthermore, any unused quota (underages) from Quota Period 1 or 2 must **not** be rolled over to increase quota in subsequent periods. Allowing harvest to accumulate into late-season surges defeats the conservation purpose of the cap. Overages in any period must be dollar-for-dollar deducted from the subsequent quota period.

3. Apply Precautionary Ecological Management to Protect Avian and Marine Wildlife

Atlantic menhaden are the foundational food source for ospreys, gannets, striped bass (rockfish), bluefish, and marine mammals. Science directly links severe osprey nest failures and chick starvation across high-salinity Bay tributaries to menhaden depletion caused by localized purse-seine harvesting. The Commission was mandated to evaluate precautionary management in response to these failures; it

must now act decisively by placing the energetic requirements of wildlife above industrial fish meal and oil processing.

4. Permanently Link the Bay Cap to Coastwide Total Allowable Catch (TAC)

The ASMFC must establish a binding link between the Chesapeake Bay Cap and the coastwide Total Allowable Catch (TAC) to ensure that any future coastwide reductions automatically trigger proportional reductions within the Bay. Industrial extraction must never be allowed to operate in essential estuarine habitats without proportional safeguards.

The ASMFC must uphold its statutory obligation to protect shared marine resources. The Commission must adopt Option B4 for a 50% Bay Cap reduction, establish strict seasonal quotas without underage roll-forward loopholes, and enforce precautionary ecosystem management.

Respectfully submitted,

Saundra Holloway

Just finished reading the article about the ospreys. We were at the Jersey shore for 3 weeks Sept 12 to Oct 3rd. We could not catch a fish in the ocean and when we fished the pier in Ship Bottom we caught very little. And I mean very small numberof fish. Over the period maybe a total of 20 snapper blues, black fish, spots and 2 small flounders. This has been the worst fishing season. The limits on the industrial fishing should be cut in half. When they net the bait they also catch other fish that end up dead.

The current harvesting of menhaden is not sustainable and is causing real harm.

The population of Osprey is in a steep decline due to industrial over harvesting of this important food source for the marine ecosystem.

I urge you to consider sharply reducing the current harvest and establish a sane, sustainable amount.

Regards,

Walter Rajczyk

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I am writing as a Maryland resident who has lived in St. Mary's County since 1990 and has developed a deep personal connection to the Chesapeake Bay. I am an avid nature lover, angler, kayaker, snorkeler and scuba diver, a conservationist, and someone who spends considerable time on and around the Bay. I have personally seen a sharp decline in the number of occupied Osprey nests visible from my house. Last year's occupancy was down to one of three occupied and this year none were occupied. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base.

I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, I urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management would provide a more precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.

There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

I respectfully urge the Commission to:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.

2. Establish firm seasonal quota periods for menhaden.

3. **Prevent excessive concentration of reduction harvest during the summer months.

4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.

5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.

We should not wait until the consequences are unmistakable before acting.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

Sincerely,

Alan Herod
St. Mary’s County, Maryland

James Boyle

Subject: [External] "Menhaden Draft Addendum II"

Categories: Menhaden 2 Auto Replied

To Whom It May Concern,

Growing up in Old Lyme, where I still reside, and spending summers on our island off the coast near Rocky Neck State Park, I have witnessed firsthand the incredible abundance of wildlife that once defined this area, particularly our osprey populations. In recent years, however, I have seen a devastating decline in menhaden, commonly known as bunker, which are a critical food source for ospreys and other marine wildlife.

As commercial fishing pressure has increased, the impact on our local ecosystem has become increasingly difficult to ignore. I have personally witnessed ospreys struggling to find food and, heartbreakingly, dying of starvation. An area that once supported thriving wildlife now feels like a shadow of what it used to be. These changes are not just numbers on a chart or statistics in a report; they are happening in the waters, marshes, and shorelines that I have called home my entire life.

We need stronger, science-based fishing regulations and meaningful protections for menhaden populations before the damage becomes irreversible. These fish are a fundamental link in our coastal food chain, and when they disappear, the consequences ripple throughout the entire ecosystem. Ospreys cannot survive without an adequate food supply, and neither can the countless other species that depend on these waters.

At what point do we recognize that our desire to harvest natural resources does not give us the right to destroy the ecosystems that sustain other living beings? We have a responsibility to be stewards of these waters, not simply to exploit them for short-term gain. Wildlife has an inherent value beyond its economic usefulness, and we have an obligation to protect the species with which we share this planet.

I fear that if we continue down this path without stronger safeguards and accountability, we will lose the very wildlife that makes this place so special. We cannot keep taking from nature without giving it the opportunity to recover. Protecting menhaden means protecting ospreys, our coastal ecosystem, and the future of the place we call home. We must act now, before what was once abundant becomes something our children and grandchildren only hear stories about.

Regards,

Allyson Gleason, Old Lyme, CT

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Greetings,

I am writing in support of lowering the catch limit for menhaden in the Chesapeake Bay. This fish is a foundation of the ecosystem, and a strong and healthy population benefit the entire ecosystem including the many people who fish and recreate within the bay area.

The current cap has led to overfishing and benefitted one corporation, and a foreign one at that, at the expense of the community.

Thank you,
Nate Hersh

Subject: [External] Public Comment: Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Atlantic States Marine Fisheries Commission,

I am writing to submit public comment regarding Atlantic Menhaden Draft Addendum II.

As an angler concerned about the health of our marine ecosystems and predator stocks, particularly striped bass, I urge the Commission to implement stronger conservation safeguards for menhaden:

1. Cut the Chesapeake Bay cap by the full 50%.
2. Link the Chesapeake Bay cap to the coastwide limit, ensuring that when the coastwide quota drops, the Bay cap decreases accordingly.
3. Spread the Chesapeake Bay harvest across quota periods to prevent localized depletion during critical spring and summer months.
4. Reduce the coastwide catch limit by 40% to align with ecological reference points and management science for 2027 and beyond.

Menhaden are vital forage for striped bass and the wider coastal ecosystem. Please adopt these measures to protect this critical fishery.

Sincerely,
David Pipolo

Subject: [External] Osprey decline

Categories: Menhaden 2 Auto Replied

To whom it may concern,

I'm writing due to the visible decline in the NJ osprey population. It is alarming to have witnessed such a steep drop in osprey numbers after seeing our local population flourish over the last decade. In my lifetime, I witnessed nesting platforms being erected to establish a healthy population- when I had never witnessed a single osprey as a child. Fast forward 30 years, a then booming population where I could see 5-6 osprey perched at the end of my beach's pier fishing all day long. Suddenly, this year, I'm lucky if I see one or two. I've been reading reports since earlier this spring about a noted decline in the osprey population; one I can confirm with my own eyes. Something has to be done. Our state has worked far too hard protecting this species, making grand efforts to make our state a safe place for them to thrive again, to let it drop off and do nothing.

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle:

I strongly support a 50% reduction in the Chesapeake Bay reduction fishery cap (Option B4/ reducing the cap to 25,500 metric tons) and support seasonal quota periods!

I live along side Cattail Creek off the Magothy River, on land that's been in my husband's family for more than 100 years. We care deeply for the Bay ecosystem and all of the creatures that call it home. For many years we have enjoyed watching the local osprey prepare a nest, raise their chicks and finally fledge with "flying lessons" from their parents before we say goodbye for the season, usually in mid-September. But for the last several years there has been no successful nesting here, which mirrors declining productivity and widespread nest failures among our Chesapeake Bay osprey population overall. Along with the stressed populations of striped bass, these declines signal an URGENT need for precautionary conservation practices NOW.

Industrial reduction fishing extracts over 100 million pounds of fish in a concentrated summer window, damaging the local food web and depriving other groups, especially watermen and anglers, of fair access.
We urge fishery managers to implement strict quota periods that will distribute the harvest evenly across the year rather than allowing an intense summer harvest.

We can't wait for the results of a study to do what needs to be done NOW. As was done with the rockfish crisis, the season should actually be closed to encourage recovery. A 50% reduction is already a compromise, a coast-wide reduction would be better still.

Please support responsible stewardship of the entire Bay ecosystem before it is too late!

Most sincerely,

Lise & Jim Crafton

Categories: Menhaden 2 Auto Replied

Greetings! As a person, I care about protecting menhaden and other marine animals.
I ask you to please safeguard menhaden and limit harvest of menhaden for the future, so that we can protect their populations. This will benefit both wildlife and human community. We can work together to increase menhaden populations.
But no doubt, if we are to improve their numbers, we must be wise and limit the harvest now. This is in the best interest of everyone for the future. Again, please take all measures necessary to increase menhaden populations, and safeguard and increase their numbers.
Thank you for your time, and have a great day! Take care, Rebecca

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

ASMFC Members,

As an Environmentalist, Conservationist, Master Naturalist, Birder, and lastly, an avid and ethical recreational angler, I **fully and strongly** support the following sections of the subject Addendum.

- **3.1 Option C1e:** Reducing the initial Chesapeake Bay Cap by 50%, from 51,000 to 25,550 metric tons.
- Establishing the Bay Cap at 13.6% of the coastwide total allowable catch so it can adjust when the coastwide quota changes.
- **3.1 C2a:** Maintaining 51,000 metric tons as the maximum Bay Cap, with no fixed lower limit.
-
- **3.2.1 B2:** Even Length & Uneven Harvest. Allocating 25% of the Bay Cap during the first quota period, 25% during the second period, and 50% during the final period.
- ***This is of particular importance to the recent evidence of unsuccessful osprey breeding and survival of hatchlings. Wildlife Biologists and birders that monitor osprey nests have confirmed poor reproduction and survival rates in recent years. I personally live on a tributary of the Choptank River and have confirmed less active osprey nests with adults and babies. Delaying 50% to the final period will increase available menhaden for adult ospreys to feed their young during their nesting period. I have also experienced a reduction in striped bass populations in the Choptank River watershed where I primarily fish recreationally.***
- **3.2.2:** Require early- season quota period overages to be deducted from the corresponding period during the following year.
- ***In my opinion, there should never be any overages.***
-
- **3.3 Option B** Revisit Provision: The Chesapeake Bay Cap and related management measures will be revisited every three years following implementation of this draft addendum.

In addition, I strongly support Virginia being required to create a 3-mile limit on reduction fishing like all the other states on the Atlantic Seaboard. We simply need to quit harvesting the Atlantic Menhaden in the Chesapeake Bay until there is scientific evidence to support harvesting there again.

Sincerely and strongly concerned,

Herbert Floyd
Trappe, Maryland

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

I strongly support the proposed 50% reduction in the Chesapeake Bay reduction fishery cap (Option B4 / reducing the cap to 25,500 metric tons) and seasonal quota periods. I hike, kayak, sail and fish on the bay from Calvert, Anne Arundel, Talbot and Dorchester Counties and am extremely concerned for the health of the Chesapeake Bay ecosystem. I have personally and casually observed a decrease in Osprey nest occupation and juvenile populations in recent years. I have learned that these issues are signs of an ecological crisis where Osprey and other predators are sentinel species and indicate an urgent need for precautionary conservation. Declining numbers of Osprey and stressed striped bass populations have been traced to industrial fishing which extracts 100 million pounds of fish in a concentrated summer window. This harms the local food web and deprives watermen and people using the Chesapeake Bay for recreation such as anglers of fair access. I urge you to implement strict quota periods that distribute the harvest evenly across the year rather than allowing an intense summer harvest.

Subject: [External] Approve Draft Addendum II - Support science-based menhaden management

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator Boyle,

My name is Jon Reynolds. I am President of South Atlantic Fishing Environmentalists. We are an organization of over 700 members, mainly composed of charter fishermen, charter clients, recreational fishermen and associated businesses. I am an active recreational fisherman, charter boat owner/operator and commercial fishermen in South Florida. The Amendment 3 PID is a very well laid out document with options that are extremely important for the future of our fisheries and interactions between ocean predators and prey. I witness these interactions on the water daily and understand just how critical it is that we leave ample forage fish in the water as food for predators. A large stock of forage fish swimming off the coast, such as menhaden, is a major factor in the success of my fishing trips.

My name is Jon Reynolds. I am President of South Atlantic Fishing Environmentalists. We are an organization of over 700 members, mainly composed of charter fishermen, charter clients, recreational fishermen and associated businesses. I am an active recreational fisherman, charter boat owner/operator and commercial fishermen in South Florida. Healthy forage fish populations are extremely important for the future of our fisheries and interactions between ocean predators and prey. I witness these interactions on the water daily and understand just how critical it is that we leave ample forage fish in the water as food for predators. A large stock of forage fish swimming off the coast, such as menhaden, is a major factor in the success of my fishing trips.
I urge the Atlantic States Marine Fisheries Commission to approve Draft Addendum II and reform menhaden management to better support the entire Chesapeake Bay ecosystem and recreational fishing.
I respectfully ask the Board to approve the following measures in Draft Addendum II:
-Options C1e and C2a, which would link the Chesapeake Bay Reduction Fishery Cap to approximately 13.6% of the coastwide total allowable catch while retaining the existing 51,000-metric-ton upper limit. At the current coastwide quota, this would reduce the Bay Cap by approximately 50%, to 25,500 metric tons.
-Option B2, which would distribute harvest across 25% / 25% / 50% seasonal quota periods and reduce the potential for concentrated fishing when forage may be especially important to predators.
-Option B, which would deduct early-period overages from the following quota period while allowing unused quota to roll forward.
A requirement to revisit the Bay Cap every three years so managers can incorporate new Chesapeake Bay-specific science and respond to our evolving understanding of menhaden and predator needs.
I also support setting the 2027b□2028 coastwide total allowable catch at a level carrying no more than a 50% probability of exceeding the Ecological Reference Point fishing mortality target. Managing menhaden to the ERP fishing mortality target achieves both ecological and economic goals by protecting the role of menhaden in the ecosystem while providing for the livelihoods of bait fishermen, tackle shop owners, guides, and all others who rely on menhaden to support recreational fisheries.
Please approve Draft Addendum II and take meaningful action to ensure that menhaden management supports a healthy Chesapeake Bay, abundant sportfish populations and sustainable recreational fishing opportunities.

Thank you for considering these comments.

Sincerely,

Jonathon Reynolds

Subject: [External] Protect Our Wildlife

Tourism in the state of New Jersey and most coastal states along the eastern seaboard is a huge industry and fills each state's coffers with tax dollars year after year. I personally have been vacationing with my family in Cape May, New Jersey for many many years. One of the thrills for each generation is observing ospreys fishing and flying by with fish in their talons.

While commercial fishing is also an industry, a balance needs to be struck. Unfettered, and unchecked commercial fishing is depleting the menhaden or Bunker stocks to record lows.

So much effort was put into bringing back these great birds after the DDT problem. Right now, the Osprey is the Canary in a coal mine. If a balance is not struck to protect and replenish the fish, other species will be harmed. And so to eventually the lucrative tourist industry.

Act now to strike a balance.

Susan Lawless, Bethlehem, PA and regular vacationer in Cape May County New Jersey.

To the Atlantic Menhaden Management Board,

I am writing to express my strong support for the most protective conservation measures outlined in Draft Addendum II.
Specifically, I ask that you cut the Chesapeake Bay Reduction Fishery Cap by a full 50%, tie this Bay Cap directly to the coastwide total allowable catch, and split the cap into seasonal quotas to prevent heavily concentrated harvesting during the spring and summer months.
Additionally, I strongly encourage the Board to establish a coastwide TAC for 2027 and beyond that successfully meets the ecological reference point target.
The 2025 stock assessment demonstrated that the population is lower than previous estimates, and the Board's own forecasting indicates that a reduction of at least 50% is necessary to achieve this goal.

Thank you for your time and consideration.

Subject: [External]

Good Evening,

My name is Brian Weiss and I write to you as a passionate and concerned sportsman, charter fisherman, and prior commercial fisherman. I was born and raised fishing the waters of long island sound and have loved the sport since the moment I was able to hold a rod and reel. Captivated by both my love of the sport and my admiration for all things wild, I have always paid close attention to the environment in which I spend most of my time.

As both a recreational angler and a working professional, attention to detail is paramount. The most important items to log and recall are the movements and behavior of the fish that you target and more importantly, what they feed on. Without a doubt the most important forage across the board is the Menhaden. If you don't know this already, you better not forget, because everything… and I mean everything eats menhaden.

From the moment that they are alive, the entire food chain relies on this baitfish and without it, I do not know where our waters would be. As a child I can remember acres of bunker from peanuts to full grown adults throughout our fishing season, and in recent years I have been both disappointed and increasingly concerned with their numbers everywhere I have fished in New England. As anglers we adapt to changes and cycles that exist in any environment to be successful, but every year that passes I see fewer and fewer bunker.

Of course, as someone who relies on healthy fisheries this concerns me, but I worry more about the effects it may have on our ecosystem that I do the money in my pocket. If you do not fully grasp the importance of this, listen closely. WAKE UP. If the population of menhaden struggles, so will everything else that swims. Everything trickles down and if something this important struggles, the ecosystem loses its equilibrium. I fear that if we do not realize this as a community, we will pass the point of no return.

Folks who don't understand the gravity of this situation or those who pad their wallets from this fishery may laugh or dismiss this concern, but nobody will be laughing if it continues to decline as we have seen in recent years. I understand that there are people who rely on this resource as a way to feed their families and fuel our economy. I also understand that there are products that are made and sold using this resource that can provide health benefits across the globe in things such as fish oil pills.

However, if we lose this, we lose everything. This same trickle down effect within the environment will also be seen economically. Forget the menhaden fishery, but all other fisheries that are influenced by this species will take a dive. Other baitfish species will be relied on for consumption as an alternative and in turn, those will too be massively effected. Businesses and communities that thrive during certain parts of the year will suffer. This includes tackle shops, fishermen, restaurants, hotels and lodging, gas

stations, and many other business that rely on the support of passionate anglers and tourists to uplift the economy during critical seasons.

If you don't care about the resource and want to continue to abuse it as long as you can, be my guest, but what follows will cripple those who rely on it and much more. If you are reading this letter, I urge you to listen and consider the repercussions of improper management moving forward. I am in full support of landing and quota period reduction. I truly believe that our waters and our people will benefit from this. I also believe that this needs to be done immediately to be successful. If we linger in the thick of political discussion, we only continue to further the damage while we do nothing. Help me believe in our system, and help our environment and economy flourish for future generations by making the right decision. I thank you from the bottom of my heart for reading my letter and hope that you consider these words moving forward.

Sincerely,

Fisheries Advocate Brian Weiss

Subject: [External] Comments on Marine Fisheries Commission Draft Addendum II

We are writing to ensure that menhaden fishery management in the Chesapeake Bay reflects ecological realities and the best available science! We support the following options in Draft Addendum II:

Section 3.1 – Chesapeake Bay Reduction Fishery Cap Amount

Options C1e and C2a: Link the Bay Cap to 13.6% of the coastwide total available catch (TAC) while maintaining a 51,000 metric ton upper limit.

- These options ensure Bay harvest remains tied to coastwide management and Ecological Reference Point (ERP) guidance.

Section 3.2.1 – Quota Periods

Option B2: Divide the Bay Cap into three quota periods (25%, 25%, 50%).

- This timing structure better protects predators like osprey during sensitive periods for their young, when energetic demands are highest.

Section 3.2.2 – Quota Period Overages & Underages

Option B: Require overages from early quota periods to be deducted from the same period the following year.

- This ensures quota periods have real meaning and accountability. If commercial fishing interests are able to exceed catch limits with impunity, the limits will have no regulatory force or ecological benefit.

Section 3.3 – Bay Cap Adjustment Provision

Option B: Revisit the Bay Cap every three years.

- This measure ensures that fishery management is tied to ecological conditions and will protect both the fish and the fishery, depending on population dynamics over time.

Support for Coastwide TAC Alignment

We also support setting the 2027–2028 coastwide TAC at a level with a 50% or lower probability of exceeding the ERP fishing mortality target.

Coastwide and Bay management must work together. If science supports reducing coastwide harvest to protect the ecosystem, **Bay harvest should reflect those same conservation goals**. Otherwise fishing pressure will continue to increase in the Chesapeake as a relative proportion of the overall coastwide harvest.

Menhaden are foundational to the Chesapeake Bay ecosystem. Not only are menhaden voracious filter feeders that clean the water of the Bay every day, but their abundance

directly affects predators such as osprey, striped bass, and marine mammals, and the Severn River's recent nest-camera data provides clear, local evidence of declines tied to insufficient abundance of food. By adopting the recommended options in Draft Addendum II, ASMFC can strengthen ecological resilience, support recreational fisheries, and safeguard the Bay's iconic wildlife!

Thank you for your consideration and for your commitment to science-based management.

Atlantic Menhaden Board:

Recently, Ault and Luo (2026) published a paper that purported to provide a new estimate of natural mortality that, if used, would substantially change the estimated biomass of menhaden in the stock assessment. They further claimed that their study was an improvement over the estimates in Liljestrand et al. (2025). Taken at face value, the Ault and Luo (2026) study casts doubt on the accuracy of the 2025 stock assessment.

As a co-author of Liljestrand et al. (2025), I have reviewed the work in Ault and Luo (2026) and found several fatal flaws such that the information in that paper should not be considered best available science. The main flaws are:

1) The models used by Ault and Luo (2026) do not produce statistically valid estimates. I have rerun their models that are publicly posted on GitHub (https://github.com/bigjawfish/Menhaden_MMR_Model) and found that they do not meet standard diagnostics for determining whether results from a Bayesian model are valid. This is not surprising because previous research on this type of model indicates that the Ault and Luo (2026) model should have problems with parameter estimation.

2) Ault and Luo (2026) ignore the empirical data on magnet efficiency from experiments that were done by putting tagged menhaden directly into the reduction plants to determine the fraction of tags that were recovered (nearly 100,000 fish in nearly

1,000 separate experiments). Liljestrand et al. (2025) used these data to inform their model, which is a better approach.

3) Ault and Luo (2026) distort the literature on the maximum age of Atlantic menhaden. Ault and Luo (2026) state, “More than five decades of ageing data encompassing over half a million Atlantic menhaden indicate that the species regularly attains ages of at least 10–11 years (Schueller et al., 2014, 2021; SEDAR 69, 2019).” That statement is misleading and incorrect. No Atlantic menhaden have been aged to age-9 or older since 1964, despite >500,000 menhaden being aged during 1955-2023. These early high ages are only present in the first ten years of the ageing program when ageing methods were still being developed, and they had a different set of agers than after 1968. A more realistic estimate of the maximum age is likely 6-8. Age 8 is the oldest observed age since 1968 with only two observations. Only twelve fish have been age-7 since 1968, and 155 fish have been aged to 6 (out of more than 300,000).

These flaws are similar to those identified by the ASMFC Atlantic Menhaden Technical Committee when they reviewed Ault and Luo’s work previously and comments (March 4, 2025) that I also made to Ault and Luo over the past several years. However, Ault and Luo chose not to address them. The stock assessment should continue to be used as the best science to manage this stock. My co-authors and I plan on submitting a rebuttal to the Ault and Luo (2026) article soon.

Sincerely,
Mike Wilberg

Subject: [External] Draft Addendum II and the Coastwide TAC

Good morning,

I am emailing you to comment on AMFSC's
Draft Addendum II and the Coastwide TAC. The population of menhaden and other forage fish in the mid Atlantic are at extremely concerning numbers and with Osprey and Striped bass recruitment numbers at all time lows these iconic creatures need as much help as we can give them. Thus I am suggesting the following adjustments:

Sec 3.1: sub option B4 - a 50% reduction in the current bay cap of 25,500 mt

Sec 3.2.1: option B1 - even length and even harvest

Sec 3.2.2: underage sub option 1 - an underage quota in period 1 would be split evenly and rolled over to quota periods 2 and 3

Sec 3.3: option B - the Chesapeake bay cap will be reviewed at least every three years

I also insist that the Coastwide TAC be dropped by 50% to 94,420mt. This is the only option that will keep the fishery from operating at an overfishing level. These numbers are backed by science and we cannot let omega proteins and others plunder our forage fish so that some people can have fish oil pills instead of just eating fish every now and then.

Thank you for your time,

-Ben Lee

I , as a cape cod born and raised angler, support all of the following:

- Cutting the Chesapeake Bay Cap by the full 50%
- Linking the Bay Cap to the coastwide catch limit, so when one drops, the other does too
- Spreading Bay harvest across quota periods so the Bay isn't stripped in spring and summer
- Reducing the coastwide catch limit by 40% to meet the science for 2027 and beyond

Thank you for your time and consideration.
Tight lines,
Collin Underhill

I oppose any reduction of menhaden harvesting. Please do not give in to mob rule. Allow science to continue to be the best driver of any decision made for this industry. I recreation fish on the Chesapeake Bay. There are more schools of bunker this year than I have seen in years. The schools of bull drum are plentiful throughout the bay. They are feeding on schools of bunkers.

Subject: [External] Coastal TAC and Addendum 2 comments

Good afternoon, I would like to comment of the upcoming menhaden regulations. My name is Lou Tirado, I run a single operator inshore charter fishing business and have done so for the last 15 years. I have also fished the coastal waters of Maine for 35 plus years. I have fond memories of an abundant menhaden fishery and I have not so fond memories of them disappearing. In recent years we have seen some reappearing of these extremely valuable forage fish, but not nearly enough, and while not may be anecdotal, I believe the lack of the forage fish has negatively affected the predator fish that rely on them. Menhaden are an integral part of the foundation of the food chain, and for too many years we have taken pieces of the foundation, so much so that we are in jeopardy of watching the whole house collapse. As far as what options I am in favor of please record the following:

3.1 Chesapeake Bay Reduction Amount-
Option B4, I would like to see a 50% reduction.

3.2.1 Chesapeake Bay Reduction Fishery Cap Quota Period -
Option B1

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota and Overages -
Option - Underage Suboption 1

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Program
Option - Option B

As far as the TAC goes, I am in favor and would like to see a 50% reduction across the board.

Thank you for your time.

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board Members,

I am writing in support of stronger protections for Atlantic menhaden under Draft Addendum II. Please reduce the Chesapeake Bay reduction fishery cap by 50%, from 51,000 to 25,500 metric tons, and keep that cap independent of the coastwide total allowable catch.

I live in Narberth, Pennsylvania, and fish from kayaks and small boats. Striped bass fishing in New Jersey and the Delaware River is part of what draws me to our region's waters. Although I live outside the Chesapeake watershed, I have a personal stake in the health of this connected coastal ecosystem.

Fishing gives me a reason to spend time outdoors, explore new places, and plan trips around the water. I'm also interested in Chesapeake getaways with my family. A bay with abundant fish and wildlife is a place we want to visit and return to. Diminished fishing and wildlife experiences would weaken that draw for families like mine.

That matters economically. Anglers and visiting families support tackle shops, guides, marinas, restaurants, lodging, and other local businesses. As a former small-business owner, I know how much repeat customers matter. When a fishery becomes less productive, the losses spread through a community; they do not end with the angler who goes home disappointed.

I recognize that coastwide stock status does not establish whether enough menhaden are available in a particular part of the Bay at a particular time. That uncertainty supports a precautionary approach while more research proceeds. We should protect forage availability now rather than make coastal communities and wildlife bear the risk of waiting.

In addition to the 50% cap reduction, I support:

- Section 3.2.1, Option B1: equal-length quota periods with equal harvest shares.
- Section 3.2.2, Underage Sub Option 1: splitting a first-period underage evenly between periods two and three.
- Section 3.3, Option B: reviewing the Bay cap at least once every three years.

Please reject options that automatically link the Bay cap to the coastwide quota. The Bay needs protections responsive to its own ecological conditions.

My daughter, Norah, is five. I want her generation to inherit waters that offer abundant fish, thriving wildlife, and viable businesses built around those resources. Please adopt meaningful protections now, alongside a separate reduction in the coastwide catch limit.

Thank you for considering my comments.

Subject: [External] Atlantic Menhaden Draft Addendum II

To whom it may concern,

I would like to provide public comment on the Atlantic Menhaden Draft Addendum II. I am a coastal fisherman in CT, and I would like to strongly suggest that the board adopt the recommendations of a full 50% cut to the menhaden cap in Chesapeake Bay. We need menhaden in the ocean to encourage a healthy coastwide fishery, and this cut is long overdue. We need to make a significant cut to encourage more menhaden production. Thank you for your time and consideration to this matter.

Subject: [External] Atlantic Menhaden Draft Addendum II

Please register my comments on the Atlantic Menhaden. I am in favor of the following:

3.1 Chesapeake Bay Reduction Fishery Cap Amount
Option C1e: To reduce the Chesapeake BayCAP by at least 50 percent in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).
Option C2a: To set the maximum upper limit in any future change at the current level of 51,000mt.

3.2 Chesapeake Bay Cap Distribution
Option B2: To establish three even length quota periods for the Chesapeake Bay Cap, distributing the harvest at 25% in period 1, 25% in period 2, and 50% in period 3.
Option B: Provides any underage of Quota Periods 1 or 2 be rolled into Period 3 of the same fishing year. Any underage in Quota Period 3 would not be reallocated. Any overages would be deducted from the same quota period in the following year.
3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B: Revisit the Chesapeake Bay Cap every 3 years.

Thank you ,
Nancy Law

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board,

I am writing to comment on Atlantic Menhaden Draft Addendum II.

I strongly support reducing the Chesapeake Bay Reduction Fishery Cap by 50% to 25,500 metric tons (Sub-Option B4). The Chesapeake Bay is an extraordinarily important nursery and feeding area, and management of industrial menhaden harvest within the Bay should reflect the Bay's unique ecological importance rather than simply following coastwide harvest levels.

I also support Option B1 for the quota period, providing for even-length periods and even harvest; Underage Sub-Option 1, under which an underage from Quota Period 1 would be divided evenly between Quota Periods 2 and 3; and Option B for the revisit provision, requiring the Chesapeake Bay Cap to be reviewed at least once every three years.

I strongly oppose linking the Chesapeake Bay Cap to the coastwide TAC. The Bay Cap should function as an independent conservation measure for the Chesapeake. A coastwide increase in allowable harvest should not automatically permit increased industrial harvest inside the Bay.

At a coastwide TAC of roughly 112,000 metric tons, leaving the current 51,000-metric-ton Bay Cap in place could allow approximately 45% of the entire coastwide harvest to occur within the Chesapeake Bay. A 25,500-metric-ton cap would instead represent roughly 23% of that TAC and is much more consistent with recent historical harvest patterns.

Menhaden are a critical forage species, and their value extends far beyond their value as a commercially harvested commodity. I urge the Board to take a precautionary approach that recognizes the importance of abundant forage to the Chesapeake ecosystem, recreational fisheries, and coastal communities.

Please support a 25,500 metric ton Chesapeake Bay Reduction Fishery Cap and reject any mechanism that automatically links the Bay Cap to the coastwide TAC.

Thank you for considering my comments.

Justin

From: Kevin Stepka <kmstepka@gmail.com>
Sent: Saturday, October 3, 2026 7:26 PM
To: Comments
Subject: [External] Atlantic Menhaden Draft Addendum II

My name is Kevin and I'm a recreational angler from Connecticut. In the past few years I have seen very few menhaden in Long Island Sound, where schools used to be a regular presence. I know this is anecdotal, but it is consistent with the declines in Chesapeake pound net CPUE and the Choptank River survey described in the addendum, and with the status of striped bass, which the addendum notes is overfished.

Because the Chesapeake is a critical nursery for the coastwide stock, I support the most precautionary options in the draft:

- **Bay Cap amount:** Option B4, a 50% reduction to 25,500 mt. I oppose any upper or lower limit structure that would allow the cap to rise or be held above that level.
- **Quota periods:** Option B2 (25/25/50%), to move harvest away from the mid-summer concentration seen in 2023 and 2024.
- **Overages and underages:** Option B (payback of period overages) without the underage sub-option, so the periods actually constrain harvest.
- **Revisit provision:** Option B, every three years.

The addendum acknowledges that data on menhaden abundance in the Bay are insufficient. Given that uncertainty and the importance of menhaden to the species anglers depend on, I ask the Board to err on the side of caution. I also ask that the Board consider the effect of this addendum together with its November decision on the coastwide TAC, since a lower Bay Cap alone may only shift effort outside the Bay.

Thank you for considering my comments.

From: Jim Bright <jamestbright@gmail.com>
Sent: Sunday, October 4, 2026 10:50 AM
To: Comments
Subject: [External] Atlantic Menhaden Draft Addendum II

To whom it may concern,

Please implement an immediate 40% reduction to the coastwide menhaden total allowable catch (the "TAC"), which applies to every state from Maine to Florida, and is separate from the Chesapeake Bay Reduction Fishery Cap that is currently under review as part of Draft Addendum II.

For guides, anglers, and small businesses that rely on healthy fisheries, a healthy coastwide menhaden stock matters beyond the Chesapeake. Menhaden are not like striped bass. Striped bass depend on the Chesapeake to spawn, but menhaden spawn along the coast from the Carolinas to southern New England. Only about one in five adult menhaden in the Northeast come from Chesapeake Bay nursery. Addendum II's Bay Cap protects that nursery. The TAC protects the coastwide spawners.

- **Cut the coastwide TAC by 40%** to approximately 112,100 metric tons for 2027 and 2028, which the ASMFC's own science projects would still result in a 40% and 50% chance of overharvest during those years.
    - Effective management action is needed now. Delays would allow the current TAC (186,840 mt) to be used for the 2027 harvest season, enabling continued unsustainable Atlantic Menhaden harvests by the commercial fishery.
    - Set the TAC as a fixed tonnage for 2027 and 2028, not a formula that adjusts automatically. Do not defer it pending further analysis.
- **Fix the Chesapeake Bay Reduction Fishery Cap at 25,500 metric tons.** At a coastwide quota near 112,000 metric tons, keeping the current 51,000-ton Bay Cap would allow roughly 45% of the coast's harvest to come from inside the Bay. A 25,500-ton cap is about 23%, in line with the 24% average since 2018.
- **Reject every option linking the Bay Cap to the coastwide TAC.** Reductions to the Bay Cap are conservation for the Bay, and should be approached as such. Linking the Bay Cap to the coastwide TAC opens the door for geographic reallocations of unused quota and for increased harvest in the future.

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board,

Hi, my name is Jackson McCrickard, and I am a recreational angler living in Virginia. I've been fishing the Chesapeake my entire life, in both Maryland and Virginia. I'm an avid striped bass and red drum angler who cherishes our resources here in the bay, as well as along the greater Atlantic coast.

Here are my public comments on the record for the Chesapeake Bay Cap:

- 3.1 Chesapeake Bay Reduction Amount. I choose option B4 - a 50% reduction in the current bay cap which would result in a new bay cap of 25,500 mt.

- 3.2.1 Chesapeake Bay Reduction Fishery Cap Quota Period. I choose option B1 - even length and even harvest.

- 3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages. I choose Underage Sub Option 1 where an underage in quota period 1 would be split evenly and rolled over to quota periods 2 and 3.

- 3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision. I choose option B. Where the Chesapeake bay cap will be reviewed at least once every three years.

In my mind, the science is currently clear. We need a 50% reduction to the current Bay Cap as there was an error in the previous natural mortality estimate used in the stock assessment. We drastically overestimated the Atlantic menhaden stock because of this natural mortality error. The bay cap has been set way too high for way too long! And it's readily apparent to folks that spend most of their time on the water. From light tackle fishing guides to large charter boat operations, everyone is experiencing less menhaden in our waters. Our osprey are starving and if this isn't the canary in the coalmine, I'm not sure what is...

It's sad seeing our bay being slaughtered by a massive industrial fishing operation. We now have the chance to at least reduce their cap to conserve the population.

Let's please put the ecosystem first and conserve menhaden before it's too late.

Respectfully,

Jackson McCrickard

The Chesepeake Bay Cap should be set to 25,500 metric tons, and should not in any way be linked to the Coastwide TAC.

Menhaden are clearly now being harvested and an unsustainable rate. Do not delay this action, this species and ecosystem is far too valuable.

Sent: Sunday, October 4, 2026 10:32 PM
To: Comments
Subject: [External] Atlantic Menhaden Draft Addendum II

To the Atlantic Menhaden Management Board,

My name is Ryan Hunter, and I am an avid saltwater angler from Chester, NY who fishes the waters of New Jersey to Rhode Island. I am writing to comment on Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden.
I urge the Board to fix the Chesapeake Bay Reduction Fishery Cap at 25,500 metric tons.
The Bay is a critical nursery for menhaden and for the predators that depend on them. At a coastwide quota near 112,000 metric tons, keeping the current 51,000-ton cap would allow roughly 45% of the coast's harvest to come from inside the Bay. A 25,500-ton cap is about 23% of the harvest, in line with the 24% average since 2018.
I also urge the Board to reject every option that links the Bay Cap to the coastwide TAC. Reducing the Bay Cap is conservation for the Bay and should be treated as its own decision. Tying it to the coastwide TAC opens the door to geographic reallocation of unused quota and to increased harvest in the future.

Menhaden are the foundation of the Atlantic coast ecosystem, and my fishing in local waters depends on healthy forage and the striped bass, bluefish, and other species that feed on it. I ask the Board to take precautionary action on the Bay Cap at the November meeting.

Thank you for considering my comments.

Sincerely,
Ryan Hunter

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Atlantic Menhaden Management Board,

I am writing in support of stronger protections for Atlantic menhaden through Draft Addendum II. I urge the Board to adopt the following measures:

- **Reduce the Chesapeake Bay Reduction Fishery Cap by the full 50%.**
- **Link the Bay Cap to the coastwide catch limit**, so any reduction in the coastwide limit automatically reduces the Bay Cap.
- **Distribute Bay harvest across quota periods** to prevent concentrated removals in spring and summer and help maintain forage availability throughout the season.
- **Reduce the coastwide catch limit by 40% for 2027 and beyond**, as part of a science-based approach to protecting menhaden and the predators that depend on them.

As a Massachusetts recreational fisherman, I care deeply about maintaining healthy forage populations along the Atlantic coast. I ask the Board to prioritize the long-term health of the ecosystem and the fisheries it supports.

Thank you for considering my comments.

Subject: [External] Atlantic Menhaden Draft Addendum II

I am fully in support of reducing the harvest of menhaden in on the east coast. I am a charter captain in Connecticut and I have seen the impact first hand of a reduced amount of menhaden. Our rivers and Long Island sound used to be stocked with menhaden but this population has dramatically reduced over the last 5 years. I whole heartedly believe what is going on in the commercial menhaden fishery is wrong and unethical. The catch limit needs to be reduced drastically to support the survival of our most important baitfish. It has also impacted the striped bass population.

Please consider what everyone is asking for in reducing the catch for menhaden.

Sincerely,
Kyle Nichols

Subject: [External] Atlantic Menhaden Draft Addendum II

Good day,

I am contacting you to support the critical reduction in Atlantic menhaden harvest. The current science supports a drastic cut in harvest due to previous overestimation in population. I have personally seen less of these fish and consequently less gamefish that rely on them as their primary food source.

I support a full 50% cap in the Chesapeake Bay and a 40% reduction in catch coastwide. Spreading the harvest over a larger period of time to allow recovery is warranted. The action must be holistic and not limited to one area.

Please use the current and future science to preserve this vital resource. Without these fish, there will be irreparable damage to ecosystems far and wide.

Thank you for your attention in this matter.

Vincent Fraccalvieri

Subject: [External] Atlantic Menhaden Draft addendum II

Good morning,

I am writing in regards to the Atlantic Menhaden Draft addendum II. Simply put, we need to drastically cut the quotas for these fish as the population numbers are unacceptable. I've been fishing the northeast for 30 years and have seen a very noticeable decline in this crucial species. Time to put the health of our fisheries and marine ecosystem above profits. Find another way to make fertilizer, fish feed, cat food and omega 3 oils. The striped bass fishery as well as dozens of other ocean life rely on pogies.

THANK YOU FOR YOUR ATTENTION ON THIS MATTER!

Hello,

I'm writing to voice my support for lowering the catch limit for the menhaden reduction fishery to in Virginia. We need menhaden to support the fish in the sea. A healthy forage stock of menhaden for the Atlantic should be the priority in managing the stock.

Sincerely, a life long New England angler.

Subject: [External] Atlantic Menhaden Draft Addendum II

Hi, my name is Chris Gatehouse and I am a life long saltwater angler who has been fishing the eastern Long Island sound and connected waters my entire life. I will be 49 this year. Bunker are the fuel that drives the engine for northeast fishing. When Menhaden are abundant the entire ecosystem thrives, from the giant tuna and sharks at the top of the food chain to the crabs and the invertebrates that clean up the mess after a feeding. Over the last few years especially there has been a noticeable decline in bunker populations locally. You used to see schools of them routinely in all of the harbors and right outside. I remember some years in the 80's when there were so many they would swim up the tidal creeks and would sometimes wind up dying up there due to oxygen depletion. While this is not ideal I'd rather see that many than none at all. I fish 3-4 days a week from May through November and so far this year I've seen one small school of adult bunker. Recently I have seen some small schools of peanut bunker moving along the beach but not nearly with the abundance we've seen historically. The lack of bunker screws up the timing of migrations and this has repercussions that affect everything in the system, including the newly abundant seals, dolphins and brown sharks that have returned to the system. Without the bunker to eat, these apex predators are starting to eat more of our gamefish. We have cleaned up the water way tremendously in my lifetime and the marine mammals and sharks we are seeing in the sound are a testament to the success of our work to clean up the water ways and protect the apex predators. If we take away their primary food source we are setting ourselves up for future imbalances. Bring the bunker back!

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear ASMFC Commissioners,

I am a recreational striped bass angler in New York, and I am writing to support stronger protections for Atlantic menhaden, particularly in and around Chesapeake Bay.

Menhaden are an essential forage species for striped bass and many other predators along the Atlantic Coast. As anglers, we see firsthand how important healthy bait fish populations are to the health of our fisheries. Protecting the forage base is an important part of rebuilding and maintaining a healthy striped bass population for future generations.

I support reducing the Chesapeake Bay menhaden harvest cap by the full 50%, linking the Bay cap to the coastwide catch limit, spreading Chesapeake Bay harvest throughout the quota periods to avoid excessive localized removals, and reducing the coastwide menhaden catch limit by 40% in accordance with the scientific recommendations for 2027 and beyond.

I understand that commercial fishing is an important industry, but management should ensure that enough menhaden remain in the ecosystem to fulfill their critical role as forage. A healthy menhaden population benefits striped bass, other predators, recreational anglers, and the overall health of the Atlantic Coast ecosystem.

Please support the strongest conservation measures in Atlantic Menhaden Draft Addendum II.

Thank you for considering my comments.

Sergio Garcia

New York recreational angler

Subject: [External] Atlantic Menhaden Draft Addendum II

I grew up around the Chesapeake Bay and on the beach in the Outer Banks. My father retired to Tilghman Island and was friends with generational fisherman, my best friend lives in Matthews on Mobjack Bay, and I helped the Center for Conservation Biology launch and manage OspreyWatch since 2012. When I was growing up in the 70's, there were no osprey or eagles because of DDT. In the 80's and 90's, my friend had osprey nesting on her dock in Mobjack Bay. I went out with local fishing guides catching stripers on the Bay, and we caught big bluefish and trout chasing menhaden up onto the beach on the OBX.

In the early 2000's, surf fishing crashed on the OBX and the surf fishing tournaments that drew hundreds of fishermen stopped catching big fish. We stopped going out on the Bay to fish because it was a lot of money for a couple of fish.

CCB launched OspreyWatch in 2012 because it was the primary research group in the world doing any osprey research, and the population on the Bay had grown to the largest nursery for osprey in the world. Osprey are a leading indicator species for global environmental health. We hoped all the people who built platforms for their osprey would want to join our citizen science project and monitor them, and that others would join us. We had large organizations like Audubon and Master Naturalists start monitoring groups, and state biologists joined to monitor their populations since nobody had money for osprey research. We grew to 10,000 nests monitored around the world.

Alarmed citizens on the Bay started reporting osprey nest failures to CCB as they watched their osprey pairs return from the southern hemisphere and then fail to produce young that successfully fledge. CCB revisited Mobjack Bay with additional research, where most of the historical osprey research has been done, and saw that the number of ospreys nesting and producing chicks were declining rapidly. In the last five years, CCB has conducted real scientific studies that have been peer reviewed and published, confirming that osprey were not able to provide enough menhaden to chicks to keep them alive. A controlled study where researchers supplemented their food showed that they could produce chicks if they had access to enough menhaden.

Then in 2023, a meeting with VIMS scientists, CCB, Maryland DNR, a sport fishing delegate and many Omega people, discussed the collapsing bait fishing business, osprey failures, and declining sport fishing. At the same time ASMFC started meeting to discuss the decline again, as they have done since the early 2000s, and determined action was needed. Throughout these clear declines in the 2000s, ASMFC actually increased TAC limits.

I have attended almost every menhaden meeting virtually since all of this started. I understand that VIMS holds primary responsibility for the science of menhaden in the Chesapeake Bay. I was stunned that they have never done anything to assess the population of menhaden. I don't know anything about fisheries science, but in avian science we document declines with actual scientifically conducted counts. CCB has spent 50 years surveying avian populations from the air and ground, and has documented numbers

for many key species that are found around coastal Virginia. There are many peer reviewed studies and annual reports done by CCB and submitted to VADWR and publications that document species counts. What I learned sitting in ASMFC meetings and researching fisheries science is that those air survey counts are available for menhaden too. All the other states on the East Coast used science to determine that menhaden had been fished out and they all closed industrial fishing. And yet, VIMS has done nothing, and there are no actual numbers for ASMFC to use to assess localized depletion. I also learned that ASMFC uses a statisical model that is based on very old data and that the model may be incorrect and way overestimated the Atlantic population of menhaden. Nobody involved has quantified the econmic damage that this has done to local economies and the sport fishing industry that has collapsed in the Bay. All of the support for Omega is dependent on the impact to their workers, and yet we have absolutely no idea what that actual impact is. These fishermen are only working four months and go on unemployment the rest of the year.

When I originally read the Mission and Vision and Values of ASMFC, I was very hopeful.
Effective stewardship of marine resources through strong partnerships
¬ Decisions based on sound science
¬ Long-term ecological sustainability
¬ Transparency and accountability in all actions
¬ Timely response to new information through adaptive management

I really thought that with all the Eastern states represented, action would happen. Your values dictate that you respond quickly when sound science sets off alarms. I told everyone that you would act quickly.

As I sat through whole meetings that made no progress, I lost hope that quick action would happen. I joined fishermen groups and learned that you have ignored their concerns for decades. I see every day Omega boats and planes chase every school of fish, go back to the dock early because they can't catch anything, and sit at the opening to the Bay, the largest nursery for THE MOST IMPORTANT FISH IN THE SEA, and catch all the fish migrating in or out.

Now you have finally opened up this issue to the general public. You have made it as confusing as possible for anyone who is not a fishery scientist. You spent several meetings discussing the osprey science, sound science, and completely ignored it in your presentations the last few weeks. Those of us who have been involved understand that we have no idea how many menhaden Omega is catching in the Bay now, and we all believe it is less than what the new cap limits, even with a 50% reduction. Even the Omega fisherman know there are no fish in the Bay in the Spring when opsrey return. They aren't even fishing anymore in May, and yet you are setting maximum catches for May and June. You discussed not allowing industrial fishing in the Bay for those months, in several meetings, and yet it is not even an option we can vote for.

You had an opportunity to avert the ecological collapse of the Chesapeake Bay, the primary nursery for menhaden, many predator fish and birds, and destroyed a large economy of citizens that depended on you. Now it is collapsing all the way up to New England. It is inconceivable that staring this disater in the face, you are still letting them take hundreds of millions of menhaden, everything that is left, out of the Bay. It would have been easy in the short term to have Omega fish 3 miles out and make a huge difference, but you didn't even consider that.

I have completed the survey to support a 50% reduction in the menhaden catch. That you will not even visit this cap for another 3 years is astonishing, but I feel certain Omega will have to shut down because there will not be enough menhaden left sooner than 3 years.

I hope it's not too late to save the Bay,
Barbara Slatcher

Good Afternoon members of the board,

Please consider the long term effects of the legislation you're proposing that on the reduction of the Menhaden population.
Lower the Chesapeake bay reduction fishery cap to 50%

Make it across the board by linking the bay cap to the coast wide total allowable catch.

Consider adding an owner/operator license allowing commercial fishermen to catch their own bait, to be able to cut mounting costs.

The research from the university of Miami shows that your natural mortality rate for these populations is even lower than you thought, even further reducing the population. These populations need to be protected so that the industries surrounding them can continue to thrive for years to come.
Thank you for considering my comments

Subject: [External] Atlantic Menhaden Draft Addendum II

To the Atlantic States Marine Fisheries Commission:

I'm writing as a saltwater angler from Newburyport, Massachusetts, with a background in marine and environmental science, to comment on Atlantic Menhaden Draft Addendum II.

It is unfortunate the change I have seen just in the past 6 years, there used to be schools of bunker even a mile or two upriver in the Merrimack I would see multiple times a week. Today they are far less common and is noticeable on the whole eastern seaboard.

Menhaden are the base of the forage chain for the striped bass, bluefish, tuna, birds, and marine mammals that make our coastal fisheries what they are. Management should reflect that ecological role and follow the best available science. It has been extremely disappointing watching the ASMFC put the interests of our fisheries behind alternative motives that have to be driving and forcing the commission to ignore scientific recommendations.

I support the following:

1. Reducing the Chesapeake Bay reduction fishery cap by the full 50%. The Bay is the primary nursery for striped bass, and concentrated removals there have outsized local impacts.

2. Linking the Bay cap to the coastwide total allowable catch, so that when the coastwide limit is reduced, the Bay cap is reduced proportionally.

3. Spreading Bay harvest across quota periods, so menhaden aren't depleted in the Bay during spring and summer when predators depend on them most.

4. Reducing the coastwide catch limit by 40% for 2027 and beyond, consistent with what the science indicates is needed.

These measures are a reasonable, precautionary step to protect a resource that the entire Atlantic coast relies on, both ecologically and economically. Thank you for the opportunity to comment.

Sincerely,
Jacob Greco

Dear the ASMFC,

As someone studying marine science in college I realize the importance of menhaden. Atlantic menhaden are a keystone species, and provide plenty of other species such as dolphins, porpoise, whales, numerous fish species including Atlantic Bluefin Tuna, striped bass, shellfish species, and more. If this species were to be overfished the western Atlantic ocean as we know it would collapse.

Subject: [External] Atlantic Menhaden Draft Addendum II

Dear Members of the Atlantic States Marine Fisheries Commission:

I'm writing to you to support in the strongest terms reducing the Chesapeake Bay reduction-fishery cap by 50 percent and establishing strict seasonal quota periods for menhaden fishing**.**

I own a house in Tall Timbers, in St. Mary's County, a place I love both for its people and for its extraordinary beauty. One aspect of that beauty is the osprey that has always nested on our neighbor's pier -- until this year when it disappeared along with other ospreys that, like me, make Tall Timbers their home. Lest you think I only care about menhaden overfishing because of the beauty of our local ospreys, I am concerned that other seabirds, striped bass and blue fish also depend on menhaden to eat and live. They too are disappearing. That not only affects the livelihood of our local fishermen, but it depletes the complex ecological web of Southern Maryland -- with who knows what consequences we are as yet unaware of. (My son is a marine biologist who studies kelp in Southern California, and the kelp has been disappearing. Who cares about kelp, you might think, but fish eat kelp and now all the fish are disappearing too).

This depletion of menhaden is because of the indifference and selfishness of one company in Virginia that sweeps up vast numbers of menhaden not even to feed people but to turn into fish oil and fishmeal for pets. One company and its associated users should not be permitted to deplete a resource so important to the rest of the ecosystem and to other Bay users.

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, not just one Virginia based fishing company.

Sincerely
--

Subject: [External] Draft Addendum, II

Dear members of the Atlantic States Marine Fisheries Commission,

Ospreys are an essential part of ecosystems in the Chesapeake Bay, Hudson Highlands, New Jersey shore region, etc. Ospreys rely on menhaden to feed themselves & their chicks.

I agree with the Chesapeake Bay Foundation which supports:

-- 3.1C;e – a 50% reduction in the allowable Chesapeake Bay harvest and a 13.6% proportional cap on the coastal harvest, referred to as TAC.

--3.2.1B2:3 which is a quota catch percentage of 25%, 25% and 50% during the three harvest periods.

Delaying the largest harvest until the last catch period will hopefully provide some time for the menhaden to grow.

I believe that the catch limits should be reviewed at least in three years.

Please pass these regulations ASAP to limit the harvest of menhaden to enable them to grow & repopulate as they are essential for the survival of osprey & other species.

Sincerely,

John Marsh

Subject: [External] Addendum II comments

Dear board members, I am a veterinarian and life long saltwater angler currently associated with Owl Moon Raptor center . I feel that in the last 2 years the osprey nesting success on the Honga river has had a very low fledging rate due to premature deaths presumed to be incited by starvation .This has been backed up by the reduced numbers of young or even adult ospreys being admitted to our center for rehabilitation . Those being admitted have been underweight and in poor physical condition which in past seasons has rarely been the case . These observations have been documented overall on the main stem of Chesapeake Bay and along the coastal areas of Delaware and New Jersey . Observations by biologists and coastal watch groups seem to concur that lack of prey species may be contributing to this situation .

ASMFC has been aware of this situation and has had some past history of kicking the can down the road with some past issues . This osprey crisis is now an emergency and must be acted on rapidly in a meaningful way . The action taken needs to be reviewed every year not as in your addendum a repeat Revisit review in 3 years . There are many arguments that state we are not sure menhaden are the issue with the ospreys that other environmental factors also exist . Our feelings are that those factors have existed previously and have been documented .

We would like to see more than less but we ask that at least the following occur ; 1 Reducing the cap on reduction fishing Chesapeake Bay harvest by 50% from 51,000 to 25,500 metric tons.
2 Establishing the bay cap at 13% of the coastal total allowable catch . 3 Allocating three quota periods or seasonal harvest in the Bay with the lowest during the spring and summer . 4 Revisit provisions on a yearly basis and not 3 years as suggested in your Addendum currently . 5 We ideally would prefer complete elimination of this reduction fishery in the bay waters and elimination of reduction fishing to beyond the 3 mile limit of the coastal waters but especially during the quota periods .
I understand my feelings as to where we determine which is the best avenue to follow is slightly different than your suggested Addendum ,something must be done now and this topic not tabled for further discussion . Thank you for your efforts .Richard Forfa DVM

Date: October 9, 2026

From:
Elizabeth Thompson

Leesburg, NJ

Dear Mr. Boyle and the Atlantic Menhaden Management Board and others:

I am writing as a concerned NJ citizen, a Citizen Scientist, a past NJ Bald Eagle Nest Observer for NJ Conserve Wildlife, a retired NJ public school educator (Aquaculture), a retired NJ Apprentice Wildlife Rehabilitator, an avid bird-watcher, and a grandmother to six young New Jersey citizens (whom I hope will get to see the full spectrum of NJ wildlife in their lifetime, to urge the Atlantic States Marine Fisheries Commission (ASMFC) to adopt strong, precautionary management measures within **Draft Addendum II**. Atlantic menhaden are the backbone of our coastal waters, serving as a critical forage fish for ospreys, whales, striped bass, and countless other marine species. They are the critical link in the sea's food chain.

I would ask for a **total moratorium on menhaden fishing**, until their populations become stable.

Some points I would like your to consider:

- FISHERIES CONSERVATION protects and restores fish stocks and aquatic habitats to ensure long-term marine and freshwater health.

- The restrictions put in place in 2012 worked! Please make that happen again.

- You say the menhaden are not overfished, but we all heard one commenter after another at the public hearings, and many other venues, that menhaden have all but disappeared along the eastern seaboard.

- There are more stakeholders in menhaden than just Omega Protein. You and the Board must see that.

- Yes, jobs in Virginia will be lost. If the menhaden harvest dries up, they will be lost anyway. Omega Protein can resolve to change. They can adapt and make oil from algae and fish-trimming and maintain the jobs in Virginia.

- 92 percent of Virginia Voters Want to Leave More Menhaden in the Chesapeake Bay (https://www.cbf.org/wp-content/uploads/2025/10/va-menhaden-survey-2025.pdf)

- Don't make this political!

I would remind you of your mission:

ASMFC's mission:

> **"Our Mission**
>
> To promote cooperative management of fisheries — marine, shell, and diadromous — of the Atlantic coast of the United States by the protection and enhancement of such fisheries, and by the avoidance of physical waste of the fisheries from any cause…" (https://asmfc.org/about/)

and

ASMFC's reason for being:

"ASMFC Overview The Commission was formed by the 15 Atlantic coastal states in 1942. The states formed the Commission to assist in managing and conserving their shared coastal resources. The states recognize that they cannot protect their citizen's interest in the resource alone. Because marine fish species move among many states, sometimes over wide ranges, each state knows it needs the cooperation of the other states in order to be successful. The Commission is nothing more, nothing less, than the place where the states come together to define what needs to be done to accomplish their mutual interests towards common goals; and to abide by majority rule in order to work together to pursue the goals. (Pg 1) *ASMFC Advisory Primer: A Guide to the Commission's Advisory Panel Process.*

Within the limitations of your survey, which I filled out on your site; I urge the Board to implement the following recommendations, I am taking advisement on my decisions from

American Littoral Society and multiple other organizations that I align with, trust, and respect:

- **Reduce the Chesapeake Bay Industrial Harvest Cap by at least 50%:** Cutting the current cap will safeguard the Bay's role as an indispensable nursery ground for juvenile menhaden, which ultimately migrate to support ecosystems along the entire Atlantic coast.
- **Establish Seasonal Quota Periods:** Spreading the allowed catch more evenly across the fishing season will prevent concentrated depletion and reduce localized ecological crises during critical wildlife feeding windows.
- **Mandate a Triennial Cap Review:** Ensure that the Bay cap is reassessed at least once every three years to integrate the latest ecological data and respond to evolving localized ecosystem needs.
- **Maintain an Independent Cap Structure:** Keep the Chesapeake Bay harvest limit independent, preventing it from being automatically tied to or inflated by changes in the broader coastwide quota.
- **Adopt Substantial Coastwide Catch Reductions:** Set 2027–2029 specifications that align directly with the ASMFC's ecosystem-based management targets, keeping more menhaden in the water to guarantee a resilient, thriving coastal food web.

One more thing I would like to share with you, a beautifully written excerpt from *The Most Important Fish in the Sea*, by H. Bruce Franklin. Hopefully, this book is NOT unfamiliar to you all, and will remind you of the bigger picture:

Franklin writes,

"First you see the birds- gulls and terns wheeling overhead, then swooping down to a wide expanse of water dimpled as though by large raindrops and glittering with silver streaks. The sea erupts with frothy splashes, some from the diving birds, others from foot-long fish with deeply forked tails frantically hurling themselves out of the water, only to fall back into their tightly packed school. More and more birds materialize as if from nowhere, and the air rings with their shrill screams. Boats too begin to converge on the scene: the boiling cloud of birds has told anglers everywhere within view that a school of menhaden, perhaps numbering in the tens of thousands, is being ravaged by a school of bluefish.

Attacking from below and behind to slash the menhaden bodies with their powerful jaws, the razor-toothed blues are in a killing frenzy, gorging themselves with the severed backs and bellies of their prey some killing even when they are too full to eat, some vomiting half

digested pieces so they can kill and eat again. Terns skim gracefully over the surface with their pointed bills down, dipping to pluck bits of flesh and entrails from the bloody swirls. Gulls plummet and fop heavily into the water, where a few splash about and squabble noisily over larger morsels. As some lift with their prizes, the squabbles turn aerial and a piece occasionally falls back into the water, starting a new round of shrieking skirmishes. Hovering high above the other birds, a male osprey scans for targets beneath the surface, then suddenly folds its gull-shaped wings and power-dives through the aerial tumult, extends its legs and raises its wings high over its head an instant before knifing into the water in a plume of spray, emerges in another plume and laboriously flaps its four-foot wingspan as it slowly climbs and soars away with a writhing menhaden held headfirst in its talons. Beneath the blues, iridescent weakfish begin to circle, snapping at small lumps sinking from the carnage. Farther below, giant but toothless striped bass gobble tumbling heads and other chunks too big for the mouths of the weakfish. From time to time, bass muscle their way up through the blues, swallow whole menhaden alive, and propel themselves back down with their broom-like tails, leaving telltale swirls on the surface. On the mud below, crabs scuttle to scavenge on leftovers" (pgs. 3-4).

Thank you for your dedication to science-based, ecosystem-first fisheries management.

Sincerely,

Elizabeth Thompson

RE: Atlantic Menhaden Draft Addendum II

To the board taking this measure into consideration,

I am writing during this public comment period to oppose any further restrictions on the harvest Atlantic Menhaden. This industry has been under constant scrutiny for the amount of fish that are removed. When you count these tiny fish by the millions, it sounds like such a large number. What I believe most people fail to take into consideration is how the environment or Mother Nature plays into this fishery. When the industry began over a hundred years ago there were small reduction plants dotted along the entire coast with no reasonable quantification of how many menhaden were harvested. Prior to 2012 there was no limit to the number of menhaden that could be harvested from the Atlantic coast. In fact, when developing the catch limits, the best information available actually came from the reduction fishery for how many menhaden were harvested. As I've been following the TAC limit and the fluctuations along with the Ecological Reference Points, one of the things that I have not heard discussed is the Predator-Prey relationship that we are all taught from a young age. When there is pressure (from the predator) the prey numbers will decline and eventually the predator numbers will decline as well, allowing the prey to rebound. What happens if the ecosystem is dependent upon these 100s of millions of fish being removed from the environment and if those fish are already "accounted for" by Mother Nature? What then happens to that environment when we abruptly stop removing those fish?

I've done some simple research on how the changes in the TAC have seemingly already affected the population based on reported fish kills along the Atlantic Coast. From this research, reduced harvest and increasing menhaden abundance may increase the likelihood that localized environmental stressors such as hypoxia, disease outbreaks, migration disruptions and crowding-related oxygen depletion are expressed as detectable mortality events.

The pattern that I'm noting is that as we are seeing reports that the fishery is healthy and the TAC is increased, we then also begin to see more or larger fish kills. This all aligns with the idea that has continuously been presented that the fishery is not overfished. In fact, I would argue that because the fishery is not removing enough fish, we are leaving too many fish in the water which is then creating these dead zones and disease outbreak events. When the quota was implemented and then expanded from 2013-2020, the largest outbreak was recorded in the Neuse River of NC in 2017 with roughly 500,000 menhaden killed. In the Ecosystem Management Era (2020-2022) we saw the TAC reduced to 194,400mt and the first large multi-state disease-associated mortality events in New York, New Jersey, and Connecticut. Currently in our increased TAC (2023-2025), we are seeing more mortality events recorded per year than any of the previous years with these events

specifically happening within the Chesapeake Bay around Baltimore Harbor. If there were no menhaden present, there would be no large menhaden fish kill. Yet, we had tens of thousands of fish that were dominated by menhaden killed in an area that is currently being argued to be scarce.

Year	Mortality Events	Management Milestone	Coastwide TAC (mt)
2012	0	ASMFC catch limits adopted	-
2013	1	Quota system begins	170,800
2014	0	Coastwide quota management continues	170,800
2015	0	TAC increase	187,880
2016	1	TAC increase maintained	187,880
2017	1	Amendment 3 adopted	200,000
2018	1	TAC increase	216,000
2019	2	-	216,000
2020	2	ERP adopted	216,000
2021	2	Northeast Vibrio mortality investigations	194,400
2022	0	Addendum I adopted	194,400
2023	1	VIMS Research Plan	233,550
2024	2	Baltimore Harbor major mortality	233,550
2025	3	ASMFC assessment update	233,550
2026	3	TAC reduced 20%	186,840

I believe that based on the loose correlations I have found through quick research, any option to make changes to the restrict the fishery would not leave more fish in the water, but would result in nature finding it's balance and still removing the excess fish thorough disease, hypoxia and crowding-related oxygen depletion events. I support more science and investigation to be sure that these changes are warranted.

I support Option A (Status Quo) for all proposed measures in Draft addendum II.

Thank you,

Melissa Thrift

Subject: [External] Approve Draft Addendum II for menhaden management

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator Boyle,

An abundant menhaden population is crucial for keeping sportfishing relevant. Fewer menhaden means fewer gamefish, which in turn means fewer fishermen. There's no point in going fishing if fish aren't available, or so scarce that it's not worth the effort. The recent decision in CCA v. State of North Carolina relied on evidence that overfishing for a species reduces the population of that species AND other species. Please don't make the same mistake that North Carolina made. Some of those fish stocks may be permanently harmed.

Sincerely,

Michael Toth

Subject: [External] Mendehan

Mr. Boyle,
I have been fishing CT, NY, RI, NJ waters for 20yrs. I also have fished the Chesapeake the last 10. I can honestly say I've noticed a sharp decline in the bunker runs. This year I have only seen one bunch in the sound and non in RI. The ospreys are dying, not breeding, the bass are thin, lobsters are fewer (they feed on that dead oily fish). Everyone on the eastern seaboard blames the Chesapeake fisheries. That's where the bass breed. That's where the menhaden spawn. You need to cut the fisheries more than you're proposing. Sub the fisherman's pay to not fish there is money for that. If you don't you will see all of the east coast fishery die with the bunker.

Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I strongly support reducing the Chesapeake Bay reduction-fishery cap by **50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden.** The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.

I have lived in St. Mary's County since 1981, my wife is 6th or 7th generation St. Mary's County, our boys are eighth generation, and our three grandchildren are ninth generation. We are fortunate to live on a family farm on Church Cove, off St. Inigoes Creek, off the St. Mary's River - we see ospreys and eagles soaring over our fields every day in season and have the entertainment of watching their territorial battles. We used to have several Osprey chicks annually fledge and migrate at the end of the season. Now, we are lucky to have one chick and the number of birds in flight has been noticeably and drastically reduced. At the current rate of decline of the various menhaden-dependent wildlife, my grandkids will be the last generation to see osprey in flight over our land, and the last to catch fish that are similarly dependent on the menhaden food source.

The evidence points to a decline in the number of menhaden that the ospreys, striped bass and other marine life in the Chesapeake watershed depend upon for their survival. This evidence is not new or revolutionary - it has been collected for years, presented for years, reviewed for years and seemingly shelved for years. This is indeed a case where time is running out. Maybe a better, apropos statement is TIME HAS RUN OUT. If you did not plan to accomplish anything in reviewing prior year data, when do you plan to really accomplish a meaningful act? IF NOT NOW … *WHEN*?

It is both *when* and *where* those fish are removed that matter. A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource. And again, the menhaden fishery, headquartered in the southern Bay, in essence fences off the menhaden from their northern Bay neighbors.

The consequences extend beyond the reduction fishery. I own a Baybuilt deadrise, am a USCG licensed Master for power and sail, and for years have recreationally fished our neighboring creeks, rivers and the Bay. I am a captain for the *Dee of St. Mary's* skipjack at Calvert Marine Museum, and regularly take out passengers (including public school students and visitors from other areas) to demonstrate the ecology, biology and yes the business of the bay Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. **A single user group should not be permitted to catch an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users. Indeed, it becomes even more selfishly catastrophic when that single user group in essence controls the access to other groups up current of them - in essence choking off the "supply" to neighboring user groups.**

For that reason, I urge the Commission to take the following actions:

• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.

• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.

• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.

• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy, the general (voiceless) citizenry and not just one Virginia based fishing company.

The Chesapeake Bay is not simply a location on a fisheries management map. It is a complex and interconnected ecosystem, and menhaden are one of its essential links.

We/you should not wait for further deterioration before taking action. There is no time for additional five-year studies to delay the decision. You have all the studies you need to make informed decisions. The evidence is there already: no outlier surprises, no epiphanies will be revealed by any more time spent on study. "STUDY" is not an effective action; "*STUDY* is a *prelude* to action. The current and projected severe drop in nesting pairs and the lack of surviving chicks will prevent effective replenishment of the species if real action, not studies, is not taken and implemented.

As someone who lives here, fishes and sails these waters, and cares deeply about the wildlife that depends upon them, I believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.

Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the wildlife that depend upon it—a greater margin for recovery. One user group, one voter bloc, one influence group has held sway over a public/societal asset - it is time for the ordinary citizens of the Chesapeake Bay estuary to be heard AND their concerns to be acted on. No more studies, no more delay, no more political/governmental inaction, no more favoring the entitled few at the expense of the general public. Take the thumb off the scale. Make a difference. To borrow a catchphrase, *SAVE THE BAY*.

Thank you for your consideration.

Sincerely,

Capt. Heath E. Warren

There's a lot to read here . I just have to say shut it down. No harvest 0-200miles from shore till the waters are packed up menhaden. Do let happen like the herring.

REDUCE MENHADEN TAC TO NO MORE THAN 114,200 MT FOR 2027-2029 AND SET CHESAPEAKE BAY CAP AT 13.6% OF THE TAC

Members of the Atlantic Menhaden Management Board,

By way of introduction, I live on the Chesapeake Bay and have fished and crabbed and swum in its waters for 75 years and still tend my crab pots. My wife and I had 10 steamed crabs two nights ago for dinner. I have 57 years of experience in natural resource management, beginning out of law school in 1969 with the National Wildlife Federation in Washington, DC.

I served in the Maryland legislature from 1978 to 1995, the last 12 years in the Senate where I chaired the Environment and Chesapeake Bay Subcommittee. In that role, I managed all environmental legislation on the senate floor, including measures dealing with fishery and wildlife management. I also taught graduate college courses in Wildlife Management, including fishery management, and in Chesapeake Bay restoration. I prepared the curriculum for both of these courses which included case studies in fishery management, including on menhaden.

I sponsored and promoted the rockfish (*Morone saxatilis*) mortarium bill that triggered Maryland's closure in 1985 that led to the Congressional law giving the ASMFC the authority to enforce rockfish quotas and other FMPs. I testified before Congress on this federal legislation. Together with Maryland's ban, this forced Virginia and other state to close down harvest. We saved the rockfish and this allowed us to reopen the fishery in 1990 under tight regulation from the ASMFC with annual quotas established each year.

Now, the rockfish is in trouble again. The lack of menhaden is the major reason why. In the 1960s-1970s, menhaden supplied 70% of the adult rockfish diet in the Chesapeake Bay. Recent dietary monitoring showed that menhaden plummeted to about 8% of the adult rockfish diet. There is compelling evidence that the overharvest

of menhaden is adversely affecting the critical availability of menhaden in the Chesapeake Bay food chain and the Bay's proper ecological functioning.

Virginia is allocated 75.21% of the Total Allowable Catch (TAC) for the entire Atlantic Coast. That is 310 million pounds of menhaden. Omega Protein is given 90.04% by Virginia which is 279 million pounds. At an average of a generous 14 ounces a fish, which is 319 million menhaden taken from other prey and allowed to feed the reduction facility in Reedville, Virginia for corporate profit.

Addendum I Quota Allocat

State	Addend Allocatio
Maine	4.80
New Hampshire	1.19
Massachusetts	2.12
Rhode Island	0.81
Connecticut	0.33
New York	0.84
New Jersey	11.00
Pennsylvania	0.01
Delaware	0.27
Maryland	1.17
Potomac River Fisheries Commission	1.09
Virginia	75.21
North Carolina	0.37

All other such reduction facilities along the east coast have been shuttered and no other state allows the purse seining operations employed for Omega Protein's reduction facility. Maryland has banned such harvest methods for more than 50 years. This reduction plant is a relic of the bad old days of unregulated harvest. Solely because of the Canadian corporation Cooke, Inc. profiteering from its ownership of this facility, the menhaden resource is being plundered as the plant's laborers and the Cooke subsidiary Ocean Harvesters' workers are being used as pawns to block proper regulation of menhaden.

The tail is wagging the dog as Cooke, Inc./Omega Protein hires top Richmond lobbyists and PR specialists to block meaningful regulations plying Virginia governors and legislators with more than $1.1 million dollars in campaign donations and even $50,000 this year to Governor Abigail Spanberger's Inaugural Committee 2026. See: https://www.vpap.org/donors/137690-omega-protein/ for a list of all such donations.

For 21 years, Omega Protein blocked all attempts for a detailed science-based stock assessment of the Chesapeake Bay menhaden population and a survey of the effects of the reduction fishery on menhaden in the Bay and overall. They continue to this day arguing to use the lack of such data as a reason for not restriction their generous harvest quotas. Most recently, Omega protein states they want the ASMFC to forego any further reductions in their allotted harvest quotas until a planned study is completed in two years.

My recommendations for the ASMFC and its Atlantic Menhaden Management Board are to:
Reduce the menhaden Total Allowable Catch (TAC) from 186,840 mt to no more than 114,200 metric tons (a 39% cut) for 2027 through 2029. This reduction to the coastwide harvest was suggested by the Menhaden Fishery Management Technical Committee. They found that scientific estimates require a reduction to 114,200 metric tons to achieve only a 50/50 probability of staying under the ecological fishing target under Ecological Reference Point-Based Management (ERP) using rockfish as the critical species affected by menhaden declines. In reality, it should be reduced to 100,000 mt to raise the likelihood of helping striped bass recover.

In reality, the reduction should be lower to have a better chance to protect striped bass which are experiencing overfishing and poor reproductive success. The lack of menhaden is at the center of this decline. Chesapeake Bay striped bass depended on menhaden for 70% of their diet in the 1970s. Recent monitoring document that menhaden has been reduced to about 8% of the adult striped bass diet.

I personally agree with the Chesapeake Bay Foundation's urgent call for a closing of the Bay reduction fishery but at least the ASMFC can do is follow the 39% reduction in the CAP and tie in a reduction in the Bay CAP—see below.

As to Addendum II to the Fishery Management Plan for Atlantic Menhaden, I join with many others including 29 Maryland legislators
(see attached letter), the Chesapeake Bay Foundation, Maryland League of Conservation Voters, Maryland Ornithological Society, and thousands of other conservationists and fishing groups in supporting these changes:

Under Section 3.1, Chesapeake Bay Reduction Fishery Cap Amount, adopt Option C1e, which would set the Bay CAP at 13.6% of the coastwide total allowable catch (a 50% reduction under the current TAC), and Option C2a, which would keep an upper limit of 51,000 metric tons for the Bay CAP.

Under Section 3.2, Chesapeake Bay CAP Distribution, adopt Option B2, which would establish three even-length quota periods and distribute harvest 25% in period one, 25% in period two, and 50% in period three, and Option B, which would establish quota-period overage payback and rollover of unused quota within a fishing year.

Under Section 3.3, Chesapeake Bay Reduction Fishery CAP Revisit Provision. Adopt Option B, which would require the Board to reassess the efficacy of these management tools every three years.

Despite Omega Protein's disinformation campaign, there are compelling indications that the overharvest of menhaden is adversely affecting the critical importance to the availability of menhaden in the Chesapeake Bay food chain and the Bay's proper ecological functioning. More than 67% of the Total Allowable Catch (TAC) for the entire Atlantic Coast is taken from other prey and allowed to feed the reduction facility in Reedville, Virginia for corporate profit.

The ASMFC and the state of Virginia allow the slaughter of up to 279 million pounds (126,526 mt) of menhaden in 2026 for this facility, with as many as 112.4 million pounds (51,000 mt) allowed to come from the Virginia Chesapeake Bay.

This compounds decades of massive removal of menhaden for the reduction fishery where menhaden are now taken to be processed into fish meal and fish oil to profit a Canadian corporation, Cooke, Inc. This deprives other fish species dependent on menhaden as a forage fish of important protein and fat resources that are of ASMFC conservation concern. These species include striped bass (overfished), bluefish (rebuilding), weakfish (depleted), and spiny dogfish (reproduction declining).

Also seriously affected are Osprey. Other avian species may be affected including Bald Eagles.

The ASMFC has solicited public comments on its Atlantic Menhaden Draft Addendum II and mine follow, but first I am compelled to address a shortcoming.

I. PAUSE THE REDUCTION FISHERY. My preference and that of most conservationists, led by the Chesapeake Bay Foundation and its fishery biologists, is to pause the Chesapeake Bay reduction harvest of menhaden completely until the stock assessment and evaluation of the impact of this reduction fishery is scientifically envaulted under the $4.5 million funding recently appropriated by Virginia and the Congress through NOAA. The Bay cap should be reduced to zero by the ASMFC when it meets in November.

There has never been a menhaden stock assessment for heavily fished Chesapeake Bay where rockfish spawning decline is alarming over the last seven years and the ASMFC has found the species overfished. Omega Protein has done all in their power to block the assessment for 21 years.

II. OSPREY REPRODUCTION IN CHESAPEAKE BAY IS IN A RADICALLY STEEP DECLINE. It is so severe it threatens a population decline of 50% in the next 10 years. According to a September 18, 2026, report by Dr. Bryan Watts: "For decades, menhaden have been considered to be a keystone prey species for the Osprey population due to their high abundance, high energy density, and schooling behavior. In some parts of the Chesapeake, the rate of delivery of menhaden to nests has declined by more than 80% since the 1980s. The shift in diet away from menhaden has resulted in a 50% decline in the energy content of osprey diets.

The combination of a reduced rate of menhaden delivery to nests and lower energy content of the diet has resulted in an increased rate of nest failure and reduced mean brood size." See Dr. Bryan Watts September 2026 Osprey reports attached.

Both rockfish and Osprey are highly dependent on menhaden as their major source of food and their diets have been substantially deprived of this protein-dense oily fish.

While this has been occurring, Omega Protein has vigorously fought and succeeded in blocking a menhaden stock assessment for heavily fished Chesapeake Bay for at least 21 years. See "Controversy sidelines proposed study of Bay menhaden" by Karl Blankenship, in the Bay Journal, January 1, 1995. See: https://www.bayjournal.com/news/fisheries/controversy-sidelines-proposed-study-of-bay-menhaden/article_ef11d04c-6931-50ff-9d85-98f70fc9b1c1.html

Now we await the $4.5 million study results. Until this two-year scientifically sound evaluation completes its stock assessment and review of harvest and its impacts including if and in what amount menhaden can be taken for reduction, the reduction harvest should be paused.

If the reduction fishery pause does not occur, when the ASMFC decides at its November meeting on a new TAC (Total Allowable Catch) for menhaden, it should decrease the TAC by at least 39% of the current 186,840 mt and that this 72,868 mt reduction be subtracted from Virginia's allotment of 75.21% of the TAC now available.

I consider these reductions in the reduction fishery more than warranted by the science available and refer you to my comments below and newly released alarming Osprey data just released in September by a Virginia scientists and Osprey expert. These reports are attached, clearly linking the radical decline of osprey reproduction to the decline of menhaden.

The ASMFC has formally emphasized adopting Ecological Reference Points (ERPs) into fishery management decisions, including in the Atlantic Menhaden Fishery Management Plan. Instead of managing menhaden for "Maximum Sustainable Yield" of the single fish stock, the ERPs limit harvest levels to ensure enough menhaden are left in the water to sustain predator populations.

For the 2025 Menhaden ERP assessment, the ERP Working Group assessed striped bass population trends and diets as rockfish and Osprey were treated as predators in the full ecosystem model that was developed to support the intermediate complexity model used for management. The full ecosystem model showed that striped bass and Osprey were two of the most sensitive species to menhaden fishing.

Furthermore, the ASMFC responds to localized ecological pressures by weighing cap reductions in sensitive areas like the Chesapeake Bay. The Bay Cap now is useless at 51,000 mt as Omega Protein and its Ocean harvesters cannot catch this bay quota and must go offshore for more and more of its harvest. The reason: they have substantially depleted Bay stocks with their massive harvests in the past. The ASMFC has noted that the Chesapeake Bay is believed to be the most important nursery for Atlantic menhaden along the east coast. Studies have shown that peak larvae entry into the Bay occurs during winter to early summer months and menhaden may feed in the Bay until late summer.

Why allow this important nursery for this keystone species to be subject to being scooped up by huge nets from purse seiners as they grow, a type of fishing banned in Maryland for 50 years? The 51,000 mt Bay cap should be zero.

The ASMFC needs to act and exercise precaution under the ERPs for menhaden with the overwhelming linkages to rockfish and Osprey reproduction declines to the lack of their major food item—menhaden. See the new Dr. Watts' Osprey-menhaden decline linkage report attached. When facing data constraints or scientific uncertainty, the ASMFC should not flinch from the clear linkages of menhaden decline to rockfish and Osprey declines.

If the ASMFC will not adopt the closure of the menhaden reduction fishery as detailed above, I support the above detailed measures.

JUSTIFICATION FOR COLSURE OF REDUCTION HARVEST OR MEASURES IN ITEMS 1. TO V1. ABOVE.

1. LACK OF CHESAPEAKE MENHADEN STOCK ASSESSMENT. While the ASMFC insists that the Atlantic population is not overfished, no evaluation or stock assessment has been conducted of local populations, including in the Chesapeake Bay. There is increasing evidence of substantial declines in menhaden in the Chesapeake Bay and other areas. The ASMFC "initiated the Menhaden Draft Addendum in response to concerns regarding declining pound net harvest and catch per unit effort in the Bay in recent years, coinciding with an increase in the concentration of reduction harvest In the summer months, and the possible downstream effects on menhaden predators."

Funds were finally allocated to conduct a $4.5 million Bay stock assessment and evaluate regional depletions as well as impacts. This will take two years and would have been completed years ago but for 21 years of opposition by Omega Protein. It makes no sense to manage the menhaden fishery in Chesapeake Bay blindly without a stock assessment and too allow 51,000 mt to be taken for reduction while a $4.5 million study is underway.

2. MARYLAND'S DRASTIC DECLINE IN MENHADEN. There is compelling evidence that the overharvest of menhaden is adversely affecting the critical availability of menhaden in the Chesapeake Bay food chain and the Bay's proper ecological functioning. Menhaden support a working fishery in Maryland, mainly by pound netters. Our watermen harvest menhaden, and our crabbers rely on them for bait.

Menhaden are not making it to Maryland waters like they once did. Since 2017, Maryland has been unable to harvest even half of its small quota. In 2024, Maryland harvested less than 10% of its TAC menhaden quota of 1.17%. This fishery has declined sharply as menhaden harvest dropped by more than 80% since 2020 and still is below 10% of the TAC quota. Menhaden fishers in Maryland simply cannot find enough menhaden to make

economic sense. This leaves crabbers, our main fishery, struggling to find affordable bait as menhaden harvesters are unable to participate in the fishery.

The Potomac River Fishery Commission (PRFC) 2025 Commercial Finfish Report documents a radical decline of pound net bait harvest in the Potomac, crashing to 169,423 pounds in 2025 down to 2.4% of the 1964-2025 average and 8.2% of the 2024 take of 2 million pounds. In 1983, 20.8 million pounds were harvested. See this data at: https://www.prfc.us/pdfs/2026/2025finfish.pdf.

The number of licensed Potomac pound netters for menhaden has stayed at a hundred for quite some time. The ASMFC should be aware of this data in making any decisions on menhaden restrictions in November,

For several years, Maryland's delegates to the Atlantic States Marine Fisheries Commission, including a DNR fisheries expert and a fisher, have decried the absence of any meaningful numbers of menhaden from Maryland's Chesapeake Bay. They believe the reason is Virginia's reduction fishery.

3. ASMFC DENIES TECH COMMITTEE 50% REDUCION IN THE TAC. The Menhaden Technical Committee reported last fall that the menhaden coastal stock assessment found that the average menhaden biomass was 37% lower along the Atlantic Coast than previously thought. The ASMFC menhaden stock assessments resulted in forecasts indicating the need for a 54% cut to the menhaden harvest to have a better than 50% chance of meeting the target population for menhaden.

Only a 20% cut was adopted for 2026 by the ASMFC Menhaden Management Board citing economic concerns for the industrial fishery. According to conservationists, this mathematical revision revealed that previous catch limits were set too high under the corrected ecological targets needed to meet the requirements of predators like striped bass, Osprey, and marine mammals.

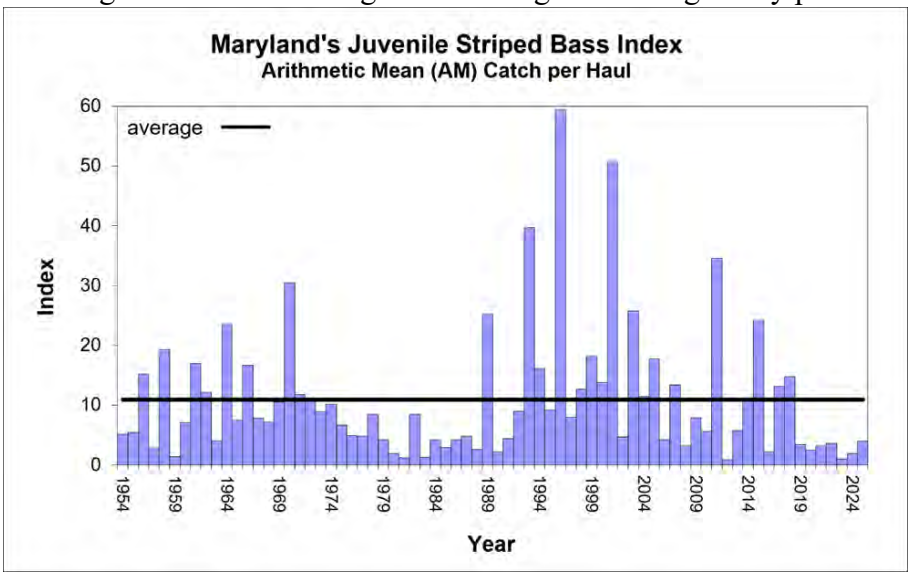
4. RADICAL DECLINE IN ROCKFISH MENHADEN IN DIET, In the 1960s-1970s, menhaden supplied 70% of the adult rockfish diet in the Chesapeake Bay. Recent dietary monitoring showed that menhaden plummeted to about 8% of the adult rockfish diet. Rockfish spawning success in Maryland has been poor for seven years in a row, and the ASMFC considers the species overfished, leading it to require significant restrictions in fishing.

***5. ASMFC DECLARES STRIPED BASS OVERFISHED, IMPOSES TAKE RESTRICTIONS*.** Maryland has been forced to cut rockfish harvest by the ASMFC. Recreationally, it has required:
January 1–April 30: Catch-and-release only.
May 1–July 31: Harvest allowed (1 fish per person per day; 19-to-24-inch slot limit).
August 1–August 31: Complete fishing closure / no targeting permitted to prevent high thermal stress and mortality.
September 1–December 5: Harvest resumes (1 fish per person per day; 19-to-24-inch slot limit).
December 6–31: Catch-and-release only.
Size/Bag Limits: Restricted to 1 fish per person per day within a tight 19-to-24-inch slot limit.
Spawning Area Closures: Major spawning rivers and designated upper Bay spawning areas (including the Susquehanna Flats and tributaries like the Choptank, Nanticoke, and Patuxent rivers) remain strictly closed to targeting from March 1 through May 31.
Gear Restrictions: Anglers are required to use inline circle hooks when fishing with bait, and specific bans remain enforced on using eels as live bait or employing trailing/stinger hooks during protected windows.

Commercially, for the 2024–2026 period, Maryland implemented a 7% reduction in the annual commercial harvest quota for striped bass from 2023 levels, complying with mandates by ASMFC. Maryland also tightened reporting by using preliminary weekly tracking to monitor commercial landings more closely.

According to NOAA, roughly 70% to 90% of the entire Atlantic coast striped bass stock spawns in the Chesapeake Bay, and young fish typically live in the Bay's tidal tributaries and shallows for their first 2 to 4 years. They often spend the first 2 years right where they were born before joining coastal migrations.

So, the Chesapeake Bay is critical not just for reproduction but also for ensuring a healthy rate of survival of juveniles before they migrate out of the Bay and join the coastal fishery. See the disastrous YOY Index with the last 7 years of reproductive success being well below the longe term average indicating a very poor outlook for rockfish in the future 5-6 years:



Source: Maryland DNR. The 2026 YOY Index is due to be released in mid-October.

6. CHARTER BOAT INUSTRY TAKES COSTLY HIT. Following the 2024 elimination of the two-fish daily limit for charter customers (reducing it to one fish), Maryland charter boats saw their harvested striped bass numbers drop from approximately 100,997 fish in 2023 down to 34,985 in 2024. Captains and industry representatives testified to a 75%–85% drop in bookings and revenue, which cascaded into bait-and-tackle shops, marinas, and guide services.

7. MARYLAND GOVERNOR DECLARES COMMERCIAL FISHERY DISASTER. In March 2023, Maryland Governor Moore petitioned the U.S. Commerce Department/NOAA to declare a commercial fishery disaster, documenting the disastrous decline of seven of Maryland's key fisheries from 27% to 91% from 2012 to 2022. This chart was submitted with Gov. Moore's request for federal money. The request was denied. Note the rockfish drop of 40% in harvest and 22% in dockside value:

Species	2022 Harvest (pounds)	Average Dockside Value (2012- 2022)	% Change Harvest Since 2012	% Change Dockside Value Since 2012
Hard Crab (blue)	22,060,449	46,051,018	-45%	-12%
Soft Crab	700,544	9,052,308	-59%	-27%
White Perch	174,751	1,089,539	-91%	-83%
Yellow Perch	31,555	75,146	-27%	-29%
Striped Bass	1,174,800	5,371,422	-40%	-22%

8. WHITE PERCH DOWN 91%. White perch, which also prey on menhaden, have seen their harvest decline by 91%. Living just off the Chesapeake, I know personally how radically this once abundant species has declined.

9. OTHER MENHADEN DEPENDENT FISH DECLINE. Fish species noted by the ASMFC as relying on menhaden as a forage fish of ASMFC conservation concern include bluefish (rebuilding), weakfish (depleted), and spiny dogfish (reproduction declining).

10. THOUSNDS OF OSPEY CHCIKS STARE TO DEATH. The cruelest, most disturbing aspect of billions of pounds of menhaden being removed for the reduction fishery from the Chesapeake and Atlantic coastal waters from Virginia to Rhode Island, is thousands of Osprey chicks starving to death in Chesapeake Bay linked to the decline in menhaden. In the 1980s, Atlantic menhaden provided 75% of Chesapeake osprey diets by weight and frequency of delivery from the mainstem saltier regions and lower sections of the Chesapeake Bay. In 2026, these important fish were reduced to less than 30% of ospreys' diets where 70% of Bay Ospreys mate and breed.

For the information on Ospreys in this document, please see Dr. Bryan Watts, Director of the Center for Conservation Biology at William & Mary, two newly published reports attached. The first was released on September 16, 2026, "Osprey Chesapeake Bay Breeding Report". The second was released on September 18, 2026, "2026 Osprey Breeding Performance Along The Atlantic Coast". So, we have the most up to date science on Ospreys before us.

11. 50% DECLINE IN BAY OSPREY PROJECTED. Dr. Watts noted in the first publication from the examination of 937 nesting pairs throughout Maryland and Virginia Bay waters. that "2026 Osprey breeding performance was the worst ever recorded for the Chesapeake Bay…Current reproductive rates are less than 50% of those recorded during the height of the DDT pesticide crisis … we would expect the breeding population to decline at an average rate of 14% per year. This annual loss rate is dramatic and without a change in course would be expected to result in a 50% decline in the population over the next decade."

12. OSPREY REPRODUCTION SUCCESS BELOW WORST DAYS OF DDT. Osprey fledging success for 70% of Bay Ospreys has dropped to a frighteningly low 0.25 fledglings per nesting pair in 2026 which is well below the ideal replacement level of 1.15 or minimum to prevent a population decline of 0.8. His data shows that in 2024 it was 0.5 and dropped to 0.35 in 2025.

13. SCIENTISTS LINK LACK OF MENHADEN TO OPSREY CHICK CRASH. Dr. Watts rebuts contentions of Omega Protein and their menhaden harvest and reduction industry PR firm and lobbyists that there is any connection between the decline in Ospreys, their chicks, and reproduction linked to a lack of menhaden.

"In 2026, as in the past several years, the factor driving widespread nesting failure was food stress.

A constellation of quantified metrics of food stress including high rates of females not laying clutches, low provisioning rates, emaciated chicks with stunted development, asymmetric broods, sequential brood reduction, shifts in mean brood size, pairs abandoning viable clutches or broods, pairs abandoning breeding areas en masse and high failure rates support this conclusion. Beyond these quantified metrics, we are observing young starve in nests.

The extreme food stress documented in recent years appears to be caused by changes in the availability of Atlantic menhaden to nesting ospreys in the Chesapeake Bay. For decades, menhaden have been considered to be a keystone prey species for the osprey population due to their high abundance, high energy density, and schooling behavior.

In some parts of the Chesapeake, ***the rate of delivery of menhaden to nests has declined by more than 80% since the 1980s. The shift in diet away from menhaden has resulted in a 50% decline in the energy content of osprey diets. The combination of a reduced rate of menhaden delivery to nests and lower energy content of the diet has resulted in an increased rate of nest failure and reduced mean brood size."***

I would also note that Dr. Watts found that 30% of adult female Ospreys failed to breed. The historic average of such failures was 2%. I have witnessed this failure to nest close to my home in Annapolis. This was the first year since I moved here in 1998 that Ospreys did not attempt to breed on their nest on Oyster Creek where I live. The nest is on the Creek and also on Chesapeake Bay.

Contentions by the profiteer propagandists plundering the keystone menhaden are fully rebutted that it is other than the lack of menhaden that is causing the crash in Osprey reproduction and populations. It is not as they again recently argued that could be other than menhaden shortages-- "storms and other adverse weather, heat stress, predation, human disturbance, contaminants, disease, parental condition, brood size, competition for prey and access to prey." This was alleged in a recent release trying to minimize any connection to the scarcity of menhaden.

I hope the ASMFC members carefully read Dr. Watts findings on this issue.

14. REDUCTION HARVEST IMPACTS YOUNG MENHADEN FEEDING IN BAY. Allowing a reduction fishery in the Chesapeake interferes with menhaden while the fish are feeding frantically and growing in the primary nursery for the coastal menhaden stock where they feed to 2 years.

15. OSPREY CHICK PROBLEMS PERSIST IN COASTAL AREAS OF MANY STATES IN SALTY WATERS WHERE MENHADEN ARE MAJOR FOOD. Recent contentions by the profiteer propagandists plundering menhaden also allege that other Osprey numbers away from the Chesapeake Bay have stopped growing or are in decline away from Chesapeake Bay.

Dr. Watts September 18 Report analyzed this and his study "Are ospreys experiencing reproductive deficits in waters beyond the Chesapeake Bay?" covered the 2026 breeding season for 2,886 pairs from 65 study areas across 10 states along the Atlantic coast. Pairs nesting within freshwater systems produced an average of 1.15 young/pair compared to only 0.59 young/pair in salty or marine systems where their primary diet consists of menhaden. The latter rate signifies population decline as found in Chesapeake Bay.

More importantly for population stability, all but one (93%) of the freshwater study sites produced more young than needed for population maintenance (minimum 0.8 young/pair), compared to only 28% (14 of 50) of saltier sites. Besides the Chesapeake Bay, regions along the coast that are experiencing reproductive deficits include the Atlantic coasts of Delaware and New Jersey, outer Long Island, the Connecticut coast, and coastal systems between Narraganset Bay Rhode Island through Buzzards Bay Massachusetts. The Atlantic Coast of the Delmarva Peninsula in Virginia is not shown because the Osprey population has collapsed by more than 90% over the past 20 years.

"Within the Chesapeake Bay food stress is driving low reproductive rates. Broods are starving in the nest. The extreme food stress documented in recent years appears to be caused by changes in the availability of Atlantic menhaden to nesting ospreys in the Chesapeake Bay…Ospreys within the Chesapeake Bay have been experiencing low reproductive rates for several years. Documentation of extreme reproductive deficits elsewhere along the Atlantic Coast is more recent. Although the underlying cause of low reproductive rates for other study areas along the Atlantic Coast is less clear, observations in numerous study areas implicate food stress and starvation as an important driving factor." See Dr. Watts' report attached.

So, the lack of menhaden in these saltier areas likely could also be driving the nest failures and Osprey chick starvation elsewhere, just as in the Chesapeake.

16. CHESAPEAKE OSPREY CRASH IS BAYWIDE. Dr. Watts' previous Osprey publications on the historic decline of Osprey breeding performance focused on Mobjack Bay (a sub-estuary of the lower Chesapeake) and the role of menhaden in driving the decline. One of the criticisms of this early work was that "Mobjack Bay only reflects conditions within a small area of the larger Bay" and is not representative of the entire Bay.

He notes in the 2026 Report how his more recent studies covered the entire Chesapeake Bay and included a survey of 937 nesting pairs throughout Maryland and Virginia Bay waters. Dr. Watts newly published data shows frightening results as well proving that the findings in Mobjack Bay are not an anomaly as Ospreys throughout the main stem of the Bay are suffering unsustainable production, most likely due to food stress from the lack of menhaden.

17. PATUXENT RIVER OSPREY REPRODUCTION CRASHING. Greg Kearns, Principal Park Naturalist at Maryland's Patuxent River Park has researched, studied, studied, and banded Ospreys on the Patuxent River for more than 40 years. He joined with Dr. Watts in his Bay-wide study.

Greg is appalled at the collapse of Osprey reproductive success. He has seen an 83% drop from 2019 to 2026 in successfully nesting Osprey pairs in his studies of the Lower Patuxent—108 to 9. The number of fledglings dropped from 201 to 12 in 2026. Of an initial 44 pairs occupied nests, only 26 produced eggs and only 9 finished 2026 with 12 chicks surviving to fledge.

There were only 0.46 chicks fledged per nest, well below the key 1.15 per nest to sustain a healthy population. Greg has spoken at the Annapolis ASMFC public hearing on Addendum II, and his work has convinced him that it is the harvest by Omega Protein that is causing the decline in Osprey reproductive success.

18. OSPREYS ARE CANARIES IN THE MINE AND INDICATIVE OF DRASTIC NEED TO CURB REDUCTION FISHERY. As Dr. Watts concluded: We should view ospreys as sentinels for the marine ecosystem rather than a species imperiled. Most osprey breeding populations throughout the world have recovered from lows driven by the DDT pesticide crisis. Ospreys appear to be secure throughout much of their range but are struggling within some coastal sites. Many of these sites have been considered to be important global strongholds for many decades. **Ospreys are apex predators and are considered to be effective indicators of aquatic ecosystem health. Recent declines in reproductive rates raise a red flag on the health of marine ecosystems along portions of the Atlantic Coast.**

19. IT IS SIMPLY WRONG TO ALLOW ONE FOR PROFIT CORPORATION TO BE ALLOWED TO TAKE 296 MILLION POUNDS OF MENHADEN, MORE THAN 67% OF ALL HARVEST. In closing, as an attorney looking at this issue from both sides, I am struck as to how and why one for profit industry is allowed to take 296 million pounds of a keystone fishery, the Atlantic menhaden. called the most important fish in the sea. Where is this a right? Yes, I know the long history of this fishery and the number of folks employed in the reduction fishery, but times have changed radically and years of taking billions of these oily fish have negatively affected viability.

Yes, one has to be sympathetic to the workers employed at Ocean Harvesters and the Reedville, VA reduction plant. Many are minorities whose families have worked there for generations. But their jobs are likely to be impacting many other jobs as rockfish and many other commercial species decline that are dependent on menhaden.

Many once super-abundant species were harvested beyond recovery: sturgeon in Chesapeake Bay (both species endangered), shad in Chesapeake Bay (closed for 40 years-once the largest by weight fishery in the Bay), the soft-shell clam whose harvest has shrunk by more than 95% in the Chesapeake, the Georges Bank Atlantic Cod Fishery (once the iconic lifeblood industry of New England, suffered an abrupt, catastrophic collapse in the early 1990s due to the rise of massive, foreign and domestic industrial factory trawlers), New England's commercial Atlantic cod fishery remains essentially shuttered, New England's Northern Shrimp Fishery prized as a regional delicacy

from the Gulf of Maine, placed under an emergency fishing moratorium by the ASMFC in 2014, with the moratorium extended repeatedly, effectively ending a centuries-old commercial harvest.

There are many more such cases. A non-fish case is the industrial whaling industry. This industry in the United States lasted for roughly 300 years, from its origins in the 17th century until the last American whaling ship departed in 1927. At its peak in 1853, the industry employed approximately 70,000 people, making it the fifth-largest sector of the U.S. economy. The industry experienced a rapid collapse after 1860. The U.S. government officially outlawed commercial whaling in 1971.

Under the U.S. Endangered Species Act, 12 whale species or distinct population segments are currently listed as endangered due to the legacy of commercial whaling including the blue whale, fin whale, sperm whale, and bowhead whale. All those whaling jobs are gone but so are most of the whales.

All of these cases in mismanagement in the name of profit and jobs should serve as an example to avoid in the ASMFC's management of menhaden.

Respectfully Submitted,

Gerald W. Winegrad

2026 osprey breeding performance was the worst ever recorded for the Chesapeake Bay

BRIEF

(Williamsburg, VA)--- The Center for Conservation Biology at William & Mary has compiled the 2026 breeding performance results for osprey in the Chesapeake Bay. The monitoring effort included 937 osprey pairs distributed among twenty-three study areas. Study areas were distributed across the salinity gradient, from tidal-fresh waters near the fall line to ocean-strength waters around the mouth of the Bay. The primary objectives for the 2026 nesting season were to assess reproductive rates and evaluate the stability of the Bay-wide osprey population based on patterns observed. Breeding pairs were monitored throughout the nesting season (March-August) to determine nesting success and productivity.

The 2026 breeding season was the worst productivity year ever recorded for osprey in the Chesapeake Bay. Average productivity in waters above 5 parts per thousand (ppt) salinity (N = 769) was 0.25 young/pair. On a global scale, the annual breeding performance required to maintain a stable population ranges from 0.8 to 1.3 young/pair. Only pairs nesting within tidal fresh waters (N = 168 nests producing 1.04 young/pair) exceeded the breeding performance threshold required for population maintenance. Eighty-one percent of all pairs nesting in waters above 5 ppt failed to fledge any young. Of pairs that did produce young, 70% were single-chick broods. The 2026 results extend the ongoing trend of productivity decline throughout saltier regions of the Bay. Productivity in the Chesapeake has dropped in recent years from 0.51 in 2024 to 0.35 in 2025 to 0.25 in 2026. Estimates of reproductive deficits should be considered conservative. We have only monitored the survival of young to fledging and there is increasing evidence that post-fledging survival may be low.

Implications for the Population

The Chesapeake Bay supports the largest osprey breeding population in the world and has been considered for many decades to be a global stronghold for the species. Given the poor reproductive rates recorded in recent years, this population is not sustainable. Current reproductive rates are

less than 50% of those recorded during the height of the DDT pesticide crisis. Based on the current demographics, we would expect the breeding population to decline at an average rate of 14%/year. This annual loss rate is dramatic and without a change in course would be expected to result in a 50% decline in the population over the next decade. However, rates of decline are expected to vary geographically within the Chesapeake. Noticeable declines in the number of occupied territories are ongoing within several study areas.

The Chesapeake Bay osprey population will not be rescued by pairs nesting within the tidal-fresh reaches of the Bay that continue to produce above maintenance levels. If we consider the minimum production threshold for stability (i.e., 0.8 young/pair), the 2026 results suggest that in order for the Bay-wide population to be stable we would need ~2.75 pairs in the area of surplus (tidal-fresh waters) for every pair in the area of deficit (>5 ppt waters). During the last systematic survey of the Chesapeake Bay osprey population (1995-1996) there were 7.5 pairs within the area of deficit for every one pair in the area of surplus.

Causes of Nesting Failures

Many factors may cause nest failures in Chesapeake osprey including storms, predation, human disturbance and heat stress. The contribution of individual factors to nest losses varies from year to year. Many of these factors have recognizable signatures in the field that do not match current observations. In 2026, as in the past several years, the factor driving widespread nesting failure was food stress. A constellation of quantified metrics of food stress including high rates of females not laying clutches, low provisioning rates, emaciated chicks with stunted development, asymmetric broods, sequential brood reduction, shifts in mean brood size, pairs abandoning viable clutches or broods, pairs abandoning breeding areas en masse and high failure rates support this conclusion. Beyond these quantified metrics, we are observing young starve in nests.

The extreme food stress documented in recent years appears to be caused by changes in the availability of Atlantic menhaden to nesting ospreys in the Chesapeake Bay. For decades, menhaden have been considered to be a keystone prey species for the osprey population due to their high abundance, high energy density and schooling behavior. In some parts of the Chesapeake, the rate of delivery of menhaden to nests has declined by more than 80% since the 1980s. The shift in diet away from menhaden has resulted in a 50% decline in the energy content of osprey diets. The combination of a reduced rate of menhaden delivery to nests and lower energy content of the diet has resulted in an increased rate of nest failure and reduced mean brood size. The underlying causes of reduced availability of menhaden to osprey are not clear. Climate change, commercial harvest, changes in distribution or delayed entry into Bay waters may be contributing factors. Ospreys require high fish abundance during April, May and June to successfully raise broods. Ospreys are unable to successfully adjust their breeding chronology when large numbers of menhaden do not arrive until late June or July.

ADDITIONAL DETAILS

2025-2026 Objectives

In recent years we have published papers on the historic decline of osprey breeding performance in Mobjack Bay (a subestuary of the lower Chesapeake) and the role of menhaden in driving the decline. One of the criticisms of this early work is that "Mobjack Bay only reflects conditions within a small area of the larger Bay" and is not representative of the entire Bay. In 2024, we collected reproductive data in ten study areas throughout the main stem (>10 ppt) of the Bay where ospreys are believed to be menhaden-dependent and two study areas within low salinity (<5ppt) reference sites where osprey depend on catfish and gizzard shad. Results from 2024 were published in Frontiers in Marine Science during the spring of 2026 (https://www.frontiersin.org/journals/marine-science/articles/10.3389/fmars.2026.1685158/full). This work showed that findings in Mobjack Bay are not an anomaly as ospreys throughout the main stem of the Bay are suffering unsustainable production most likely due to food stress. The 2024 season also showed that pairs within low-salinity areas were producing above maintenance levels.

The objective of fieldwork in 2025-2026 was to evaluate whether or not the low reproductive rate in the main stem (>10 ppt) of the Bay represents a risk to the broader Bay-wide osprey breeding population. To evaluate the metapopulation dynamics we needed to understand the relative magnitudes of reproductive deficits and surpluses across subpopulations.

Study Areas

The study area included the tidal reach of the Chesapeake Bay from the fall line (landward extent of tidal influence) to the Atlantic Ocean. The study area was subdivided into salinity zones to ensure adequate coverage of conditions. Salinity zones included low salinity (0–4.9 ppt), low mesohaline (5.0-11.9 ppt), high mesohaline (12.0–17.9 ppt) and polyhaline (18.0–30.0 ppt). Specific study areas by salinity zone include **low salinity** – Upper Chester River, Upper Patuxent River, Upper Potomac River and Upper James River, **low mesohaline** – Lower Chester River, Severn River, Upper Rappahannock River, Lower Patuxent River, Colonial Beach, Middle Rappahannock River, Middle York River, and Middle James River, **high mesohaline** – Choptank River Vicinity, Lower Rappahannock River, Piankatank River, Lower York River, Lower James River and Elizabeth River, **polyhaline** – Bayside Eastern Shore, Mobjack Bay, Lower York River, Poquoson River and Lynnhaven River.

2026 osprey breeding performance along the Atlantic Coast

Some populations are reproducing below limits for sustainability

(Williamsburg, VA)--- The Center for Conservation Biology at William & Mary has compiled the 2026 breeding performance results for osprey populations along the Atlantic Coast of North America. Within the Chesapeake Bay, breeding performance in ospreys has been poor for several years due to extreme food stress during the nesting season. Productivity has declined to critical levels that now threaten the stability of the largest osprey breeding population in the world. The primary objective for compiling osprey monitoring results for the broader Atlantic coast is to visualize breeding performance at scale and address the question "Are ospreys experiencing reproductive deficits in waters beyond the Chesapeake Bay?" The 2026 effort includes monitoring results for 2,886 pairs from 65 study areas across 10 states (Table 1, Figure 1).

Maintenance Reproductive Rates for Osprey

On a global scale, the annual breeding performance required to maintain a stable osprey population ranges from 0.8 to 1.3 young/pair depending on the specific location. We adopt the most optimistic (0.8 young/pair) reproductive rate as the "break even" threshold. The monitoring effort compiled here includes data from a wide variety of sources including academic institutions, government agencies, NGOs and private citizens (Table 1). Our focus is on breeding outcomes of the 2026 season rather than on clutch sizes, hatching rates, etc. Although nest visitation schedules varied somewhat between monitoring programs, we included only data sets that provided clear season outcomes. Estimates of reproductive rates should be considered optimistic. We have only monitored the survival of young to fledging and there is increasing evidence that post-fledging survival may be low. In addition, some programs only monitored pairs that made breeding attempts which in some populations may underestimate the population size and by doing so overestimate reproductive rates (Table 1).

Breeding Performance

The coast-wide sample of 2,886 pairs collectively produced 1,936 young resulting in an average reproductive rate of 0.67 young/pair. Success rate (portion of pairs that fledged at least 1 young) was 44.5%. Breeding performance was influenced by salinity. Fifteen study areas (405 pairs) were located within freshwater or tidal fresh systems and 50 study areas (2,481 pairs) were located within tidal waters (coastal marine) with salinities above 5 parts per thousand (ppt). Pairs nesting within freshwater systems produced an average of 1.15 young/pair compared to only 0.59 young/pair in salty or marine systems. More importantly for population stability, all but one (93%) of the freshwater study sites produced more young than needed for population maintenance (minimum 0.8 young/pair, see below) compared to only 28% (14 of 50) of saltier sites. Regions along the coast that are experiencing reproductive deficits include the Chesapeake Bay, the Atlantic coasts of Delaware and New Jersey, outer Long Island, the Connecticut coast north of the Quinnipiac River and coastal systems between Narraganset Bay Rhode Island through Buzzards Bay Massachusetts (Figure 2). The Atlantic Coast of the Delmarva Peninsula in Virginia is not shown because the population has collapsed by more than 90% over the past 20 years.

Several regions along the coast stand out for producing either very high or very low productivity. Regions reporting large deficits (<50% of requirement for population maintenance) in productivity include the Chesapeake Bay, the outer coast of Delaware and the area from the mouth of Long Island Sound to Westport River in Massachusetts (Figure 3). If these deficits continue, populations are expected to decline at an average rate of ~10%/year. Regions on the outer coast that reported good productivity include the Hilton Head Island in South Carolina, the southern coast of Connecticut and the offshore islands of Nantucket and Martha's Vineyard in Massachusetts.

Chesapeake Bay continues to be ground zero

Sixteen study areas experienced extreme deficits (below 25% of maintenance levels) in reproduction during the 2026 breeding season (Figure 4). Fifteen of these sites were located in the saltier portions of the Chesapeake Bay. Based on the current demographics, we would expect the breeding populations within these study areas to decline at an average rate of 14%/year. This annual loss rate is dramatic and without a change in course would be expected to result in a 50% decline in these population over the next decade. Ospreys within the Chesapeake Bay have been experiencing low reproductive rates for several years. Documentation of extreme reproductive deficits elsewhere along the Atlantic Coast is more recent.

Causes of Nesting Failures

Many factors may cause nest failures in ospreys including storms, predation, human disturbance and heat stress. The contribution of individual factors to nest losses varies from year to year. Many of these factors have recognizable signatures in the field. Within the Chesapeake Bay

food stress is driving low reproductive rates. Broods are starving in the nest. The extreme food stress documented in recent years appears to be caused by changes in the availability of Atlantic menhaden to nesting ospreys in the Chesapeake Bay. For decades, menhaden have been considered to be a keystone prey species for the osprey population due to their high abundance, high energy density and schooling behavior. In some parts of the Chesapeake, the rate of delivery of menhaden to nests has declined by more than 80% since the 1980s. The shift in diet away from menhaden has resulted in a 50% decline in the energy content of osprey diets. The combination of a reduced rate of menhaden delivery to nests and lower energy content of the diet has resulted in an increased rate of nest failure and reduced mean brood size. The underlying causes of reduced availability of menhaden to osprey are not clear. Although the underlying cause of low reproductive rates for other study areas along the Atlantic Coast is less clear, observations in numerous study areas implicate food stress and starvation as an important driving factor.

Imperiled Species vs Ecosystem Indicator

We should view ospreys as sentinels for the marine ecosystem rather than a species imperiled. Most osprey breeding populations throughout the world have recovered from lows driven by the DDT pesticide crisis. The North American' population has surpassed historic benchmarks largely because pairs have colonized reservoirs created within inland areas. Ospreys appear to be secure throughout much of their range but are struggling within some coastal sites. Many of these sites have been considered to be important global strongholds for many decades. Ospreys are apex predators and are considered to be effective indicators of aquatic ecosystem health. Recent declines in reproductive rates raises a red flag on the health of marine ecosystems along portions of the Atlantic Coast.

Figures

Figure 1. Distribution of study areas with available osprey monitoring data for the 2026 nesting season. Monitoring was conducted by a wide range of contributors. Data presented includes 2,886 nesting pairs within 65 study areas across 10 states. Colors denote whether or not pairs exceeded the reproductive rate (0.8 young/pair) required for population maintenance.

Figure 2. Distribution of study areas within waters above 5 ppt salinity. Colors denote whether or not pairs exceeded the reproductive rate (0.8 young/pair) required for population maintenance.

Figure 3. Distribution of study areas with large (<50% of maintenance levels) deficits in reproductive rate.

Figure 4. Distribution of study areas with large (<50% of maintenance levels) deficits in reproductive rate.

Table 1. Results of osprey monitoring results along the Atlantic Coast for the 2026 breeding season. Reproductive rate values are means ± standard errors.

[1]Reproductive estimates were based on active nests (pairs making breeding attempts) rather than all pairs in the population. These study areas underestimate breeding populations and by doing so overestimate reproductive rates.

In Dr. Bryan Watts second Osprey research paper (attached), “Are ospreys experiencing reproductive deficits in waters beyond the Chesapeake Bay?”, he covered the 2026 breeding season for 2,886 pairs from 65 study areas across 10 states along the Atlantic coast. Pairs nesting within freshwater systems produced an average of 1.15 young/pair compared to only 0.59 young/pair in salty or marine systems. The latter rate signifies

population decline. These saline areas are where menhaden dominate Osprey food supplies as found in Chesapeake Bay.

“Ospreys within the Chesapeake Bay have been experiencing low reproductive rates for several years. Documentation of extreme reproductive deficits elsewhere along the Atlantic Coast [outside of Chesapeake Bay] is more recent. Although the underlying cause of low reproductive rates for other study areas along the Atlantic Coast is less clear, observations in numerous study areas implicate food stress and starvation as an important driving factor.”

So, the lack of menhaden in these saltier areas could also be driving the nest failures and Osprey chick starvation elsewhere, just as in the Chesapeake.

“Regions along the coast that are experiencing reproductive deficits include the Chesapeake Bay, the Atlantic coasts of Delaware and New Jersey, outer Long Island, the Connecticut coast north of the Quinnipiac River and coastal systems between Narraganset Bay Rhode Island through Buzzards Bay Massachusetts (Figure 2). The Atlantic Coast of the Delmarva Peninsula in Virginia is not shown because the population has collapsed by more than 90% over the past 20 years.”

THE MARYLAND GENERAL ASSEMBLY
ANNAPOLIS, MARYLAND 21401

September 25, 2026

Commissioner Mike Luisi
Director, Fishing and Boating Services
Maryland Department of Natural Resources
580 Taylor Avenue B-2
Annapolis, MD 21401

Commissioner H. Russell Dize
P.O. Box 165
5423 Rude Avenue
Tilghman, MD 21671

Commissioner Del. Dana Stein
C/O Commission Proxy Allison Colden, Ph.D.
Maryland Executive Director
Chesapeake Bay Foundation
6 Herndon Ave
Annapolis, Maryland 21403

Dear Maryland Atlantic States Marine Fisheries Commissioners and Proxies:

We write to urge you to support the adoption of necessary conservation measures in Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden. Menhaden are essential to the Chesapeake Bay ecosystem, the people and communities that work our waterways, and many of the species who call our state home. Maryland is already experiencing the effects of a diminished menhaden population, and it is time for the Commission to act.

Menhaden are small, nutrient-dense fish that serve as a vital food source for many of the Bay's most treasured species, but they also support a working fishery in Maryland. Our watermen harvest menhaden, and our crabbers rely on them for bait. That fishery has declined sharply. Maryland's menhaden harvest has fallen by more than 80 percent since 2020 and now sits below ten percent of the quota the State is allowed to take. Crabbers are struggling to find affordable bait and harvesters are unable to participate in the fishery.

At the same time, Chesapeake Bay wildlife are showing signs of strain. Osprey chicks are starving at unprecedented levels in parts of the Bay where the birds depend heavily on menhaden for food, and the 2026 breeding season was the worst on record. Taken together with what our watermen are seeing, there is considerable evidence that menhaden availability in the Chesapeake Bay is in serious decline – much to the detriment of Marylanders and the Bay’s frontline species.

The way menhaden are managed in the Bay has not been adjusted in accordance with these changes, and it must be. The Bay Cap has remained at 51,000 metric tons since 2018, even as the coastwide total allowable catch has changed, and oftentimes more than half of the Bay’s reduction fishery's annual

landings occurred within a dangerously concentrated 6-week stretch. The conservation measures available in Draft Addendum II give us the opportunity to ensure the long-term sustainability of menhaden. Specifically, we support:

- **Section 3.1, Chesapeake Bay Reduction Fishery Cap Amount.** Option C1e, which would set the Bay Cap at 13.6 percent of the coastwide total allowable catch, a 50 percent reduction under the current TAC, and Option C2a, which would set an upper limit of 51,000 metric tons for the Bay Cap — the current level.

- **Section 3.2, Chesapeake Bay Cap Distribution.** Option B2, which would establish three even-length quota periods and distribute harvest 25 percent in period one, 25 percent in period two, and 50 percent in period three, and Option B, which would establish quota-period overage payback and rollover of unused quota within a fishing year.

- **Section 3.3, Chesapeake Bay Reduction Fishery Cap Revisit Provision.** Option B, which would require the Board to reassess the efficacy of these management tools every three years.

We are confident these changes would leave more menhaden in the Bay for the Maryland watermen and wildlife who depend on them, and serve the best interest of our state. Thank you for your attention to these concerns and your work on this important issue.

ASMFC Draft letter #1

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I am writing as a Maryland resident who has lived in St. Mary's County since 1998 and has developed a deep personal connection to the Chesapeake Bay. I am an avid fisherman, citizen scientist, and someone who spends considerable time on and around the Bay. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base.

I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, I urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management would provide a more precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.

There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

I respectfully urge the Commission to:

1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.

2. Establish firm seasonal quota periods for menhaden.

3. **Prevent excessive concentration of reduction harvest during the summer months.

4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.

5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.

We should not wait until the consequences are unmistakable before acting.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

Sincerely,

Chandler C. Wyatt
St. Mary’s County, Maryland

Subject: [External] Bunker

Mr Boyle,
I strongly support a large reduction in the harvesting of bunker. I have lived on the ocean front of LBI for over 40 years during which time I have frequently observed large schools of bunker. In the last 2 years I have not seen a single school. Additionally, the Osprey population has also decreased substantially.
I realize these are anecdotal observations, however, with other available information,I believe we must act to rebuild the bunker population.
Thank you.

I support cutting the Chesapeake bay cap by a full 50%.
Link the bay cap to the coastwide catch limit.
Spreading the bay harvest across quota periods.
And also reducing the coastwide catch limit by 40%.

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

Thank you for considering strong provisions to protect the menhaden population in the Chesapeake Bay in your Menhaden Draft Addendum II. I would ask you to approve the following options:

Section 3.1 Bay Cap Amount: Option C1e and Option C2a to reduce the Bay Cap by 50% among other provisions.

Section 3.2 Bay Cap Distribution: Option B2 and Option B which would establish 3 even length but uneven quota periods among other provisions.

And Section 3.3 Bay Cap Revisit Provision: Option B which would require revisiting the Bay Cap every 3 years.

There is more than adequate evidence that the menhaden population in the Chesapeake Bay is at great risk and that these strong provisions under consideration are required to support the menhaden population in the Bay.

Sincerely,

Michael Landen

Please reduce Chesapeake Bay Menhadden Catch Cap by a minimum of 50% in order to enable Osprey to feed their chicks. The majestic Osprey are an integral part of our Eastern ecosystem and should not be starved to death to make fertilizer. Thank you for the important work you do.

Subject: [External] Osprey decline

Categories: Menhaden 2 Auto Replied

To whom it may concern,

For years the ospreys have been in decline due to the overfishing of menhaden. Sadly this has been ignored due to the interest of the fishing industry and those that selfishly support those interests.

Over and over again the economics, jobs, jobs, jobs, have been the excuse to continue overfishing. The writing has been on the wall for years that this industry needs to be scaled back to levels that support the total environmental for effective management.

It says very little for a commission that allows profit to trump the concerns of the public that want our wild birds to not just survive but flourish.

Stop Omega from destroying our ospreys.

Respectfully,
Patricia Scanlon
Norfolk, Virginia

Subject: [External] Atlantic Menhaden Draft Addendum II - Ocean TAC

Categories: Menhaden 2 Auto Replied

Hello

Thanks for taking time to review my feedback on the menhaden fishery. I'm a passionate recreational fisherman from Rhode Island. I've helped friends commercial fish from time to time and support appropriate conservation actions to protect the fishery for the future. The commercial fishery is important and so is the recreational fishery. The economic impact of a strong recreational fishery is crucial to Rhode Island and other coastal areas. Marinas, fuel, guides, tackle shops, and the marine trade industry overall support a tremendous number of jobs in these communities.

As you consider the options for Menhaden, please remember that less menhaden need to be removed from the ocean. The data and observations is clear on that. The Ocean TAC should be reduced to at least 110 MT or a 39% drop from the current level. Menhaden, the fish and birds that forage on them, and the broader fishing community (commercial and recreational) need this to happen. Failure to act now will make future cuts more drastic and lead to a slower recovery time which is detrimental to all stakeholders.

While I'm also concerned about the Chesapeake Bay harvest and support a reduction to the bay cap, not lowering the overall ocean TAC would be a complete failure and negatively impact the fishery and those that rely on it.

Thank you for your consideration

Sean DeFusco

Subject: [External] Atlantic menhaden comment

Categories: Menhaden 2 Auto Replied

Please register my comments on the Atlantic Menhaden. I am in favor of the following:

3.1 Chesapeake Bay Reduction Fishery Cap Amount
Option C1e: To reduce the Chesapeake BayCAP by at least 50 percent in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).
Option C2a: To set the maximum upper limit in any future change at the current level of 51,000mt.

3.2 Chesapeake Bay Cap Distribution
Option B2: To establish three even length quota periods for the Chesapeake Bay Cap, distributing the harvest at 25% in period 1, 25% in period 2, and 50% in period 3.
Option B: Provides any underage of Quota Periods 1 or 2 be rolled into Period 3 of the same fishing year. Any underage in Quota Period 3 would not be reallocated. Any overages would be deducted from the same quota period in the following year.
3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B: Revisit the Chesapeake Bay Cap every 3 years.

Thank you ,
Amanda Dewey

Categories: Menhaden 2 Auto Replied

Dear Fisheries Managers:

As a lifelong resident of the Chesapeake Bay region, and a resident of coastal Virginia, I would like to state my opposition to linking the Chesapeake Bay Cap for Atlantic Menhaden, and the Coastal TAC for Atlantic Menhaden.

The Chesapeake has a special role as a nursery for osprey, shark, redfish, striped bass, and other species. It is incredibly important to not link the coastal and bay fisheries, as this would enable localized depletion by industrial fishing fleets.

Regards,
Matt Roach
Hungars Creek, VA

Subject: [External] Atlantic Menhaden 2027-2028 TAC

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission,

I am writing to submit my comment regarding the coastwide Atlantic menhaden TAC for 2027 and 2028. I support reducing the coastwide TAC by 40%, to approximately 112,100 metric tons, and believe this action should be taken now rather than delayed.

The ASMFC's own recent projections show the need for a substantial reduction. Keeping the current 186,840-metric-ton TAC would carry a 99.5% chance of exceeding the ecological reference point fishing mortality target in each year from 2027 through 2029. Even reducing the TAC to approximately 114,200 metric tons would only bring the chance of staying below that target to roughly 50%. A 40% reduction to approximately 112,100 metric tons would therefore be a necessary management action based on the information currently available.

I am also concerned about continuing to delay meaningful reductions in harvest. In 2025, the ASMFC's science indicated that a reduction of 50% or more was needed to reduce the risk of exceeding the ecological target. The Board ultimately adopted a 20% reduction for 2026 only. Given the commercial fishery's recent underutilization of the TAC, that reduction did not necessarily translate into a comparable reduction in the number of menhaden actually harvested.

Menhaden are an important forage fish throughout the Atlantic coast and play an important role in the broader marine ecosystem and recreational fisheries. This is therefore not only a Chesapeake Bay issue. The coastwide TAC affects menhaden harvest from Maine to Florida and has implications for the fish, wildlife, anglers, guides, and coastal communities that depend on healthy marine ecosystems.

For these reasons, I respectfully ask the ASMFC Atlantic Menhaden Management Board to reduce the coastwide TAC by 40% to approximately 112,100 metric tons for 2027 and 2028. I also ask that the TAC be established as a fixed tonnage rather than an automatic formula and that this decision not be delayed for additional analysis. The current science provides enough information to take meaningful action now.

I believe the Commission should use the information currently available to establish a coastwide TAC that better accounts for the ecological importance of Atlantic menhaden and the many fisheries and coastal communities that depend on them.

Thank you for considering my comment.

Sincerely,

Brendan Curley

Subject: [External] tlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission,

I am writing to submit my comment on Draft Addendum II concerning the Chesapeake Bay Reduction Fishery Cap. I support establishing a fixed Chesapeake Bay cap of 25,500 metric tons and rejecting options that would automatically link the Bay cap to the coastwide Atlantic menhaden TAC.

The Chesapeake Bay is an important nursery area for Atlantic menhaden, and maintaining a reasonable limit on harvest within the Bay is an important part of protecting that ecosystem. At a coastwide TAC of approximately 112,000 metric tons, keeping the current 51,000-metric-ton Bay cap would allow roughly 45% of the coastwide harvest to come from inside the Chesapeake Bay. A 25,500-metric-ton cap would represent approximately 23% of the coastwide harvest, which is much closer to the roughly 24% average share since 2018.

I also ask the Commission to reject options that link the Chesapeake Bay cap directly to the coastwide TAC. The Bay cap should be treated as a separate conservation measure for the Chesapeake Bay rather than simply increasing or decreasing automatically with the coastwide quota. Linking the two could create opportunities for unused quota to be shifted geographically and could allow harvest in the Bay to increase again in the future.

I also support the proposed three-year revisit of the Bay cap. Establishing a 25,500-metric-ton cap now does not mean that the Commission can never reconsider it. A scheduled review after three years provides an opportunity to evaluate new science, harvest levels, menhaden abundance, and the ecological effects of the cap before making any future changes. I believe this is a more responsible approach than tying the cap automatically to changes in the coastwide TAC.

As someone who cares about the health of Atlantic fisheries and the recreational fishing communities that depend on them, I believe the Chesapeake Bay cap should provide a meaningful and consistent limit on reduction fishery harvest within the Bay while still allowing the Commission to revisit the measure based on the best available information.

I respectfully ask the Atlantic Menhaden Management Board to establish the Chesapeake Bay Reduction Fishery Cap at 25,500 metric tons, reject all options that tie the Bay cap to the coastwide TAC, and retain the three-year review so the measure can be evaluated using updated science and management information.

Thank you for considering my comment.

Sincerely,

Brendan Curley

Subject: [External] Public Comment: Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle and Members of the Commission,

I am writing to urge the Atlantic States Marine Fisheries Commission to take immediate, strong action to protect the Chesapeake Bay ecosystem by implementing strict catch limits under Atlantic Menhaden Draft Addendum II. Specifically, I support options that substantially lower the reduction fishing allowance in the Bay.

As a resident & supporter of the Chesapeake Bay region, plus an environmental educator, I am deeply alarmed by the unprecedented breeding failures and starvation currently devastating our local osprey populations. Decades of scientific monitoring show a direct link between the lack of mature Atlantic menhaden and the inability of ospreys to successfully raise their chicks.

Menhaden are the ecological backbone of the Chesapeake Bay. Allowing industrial-scale reduction fishing to deplete this critical forage fish at the expense of ospreys, striped bass, and other native wildlife is unsustainable and unacceptable.

Please prioritize the long-term health of the Bay's ecosystem over short-term commercial harvest by implementing the maximum possible protections in Draft Addendum II. Thank you for your time and consideration of these comments.

Sincerely,
Katey Nelson

The constant excuses put forward by the fishing industry to force communities to choose between protecting natural resources and their ability to make money is again wrecking our environment WHICH IS NOT REPLACEABLE.
Overfishing combined with the current administrations penchant for deregulation clearly will permanently impact the local environment, flora and fauna.
Ospreys are a natural indicator of a healthy environment. The current catch allowances in addition to environmental changes which have been looming, may have done so much damage it cannot be reversed.

My name is Jeffrey Lopez and I am a Rockaway Park Queens New York 11693 resident and avid fisherman. I am obviously very connected to and very concerned with the declining welfare of our Osprey populations that I have witnessed over the past several years. The ChesPeak Bay harvest needs to be better managed....and there needs to be a cap of at least 50%, and managed more evenly across the entirety of the season, and create a coastwide catch reduction that meets the ASMFCs ecosystem target.

Subject: [External] Atlantic Menhaden TAC reduction

Categories: Menhaden 2 Auto Replied

Hi,

I am a lifelong fisherman and charter fishing captain based in Fairfield and Groton Connecticut. It's my opinion that Atlantic Menhaden TAC should be reduced by 50%.

Our fishery in Long Island Sound and East of Connecticut is on the brink of collapse due to extreme commercial overharvesting of Atlantic Menhaden, the foundational building block of our Saltwater ecosystem. It's been apparent for several years now that the lack of Menhaden has weakened our fishery and hurt my personal charter fishing business. Striped bass that would take residence in my waters no longer have an abundant food source, so they no longer reside here... It's just common sense, not some anecdotal observation. The commercial overharvest of menhaden has also caused many other problems, including inundation of sharks foraging on our striped bass instead of Menhaden, as well as striped bass foraging on other managed species. This is a chain reaction as a result of the negligent mismanagement of Atlantic Menhaden. Enough is enough.

I understand Omega Protein and Cooke industries has a lot of money to donate and throw around, but you must act and do the right thing. Reduce TAC for Atlantic Menhaden by 50% or more as so much damage has already been done.

Thank you,

Captain Ben Burdine

To Whom it May concern,

I am writing today to support a cap on bunker fishing off our coastlines here in Queens NY.

My family and I live on the shore. A wonderful part of having my young children grow up here is the access to our natural resources. Whether it be the Ospreys, dolphins, whales, or fish, our communities benefit from this exposure. Overfishing is leading to a decline in these species and the variety of nature around us. We noticed it this summer.

Please pass sensible and pragmatic rules that allows the bunker population to rebound. It would mean a lot to us and our communities.

Thank you,

Jay Gorman

Please pass the Atlantic Menhaden Draft Addendum II rule to reduce total menhaden allowed catch by 50% in the Chesapeake. The negative impact on the bay is reflected by many studies. While the industry may argue the numbers and the assumptions behind them, there is no doubt about the number of people who would benefit from a base forage supply that was even a small percent larger than it is today:
Most conservatively, there are roughly 2500 commercial watermen and approximately 200 (150-300) licensed fishing guides in Virginia who would benefit.
Maryland's portion brings the commercial total to 8,000 and guides to 700.
The menhaden fishery supports 250 employees. These people deserve opportunity and support to transition, but as it stands today, their work has a disproportionate impact on the ecosystem and economics of the region.

I am favor of substantially reducing the cap on industrial menhaden fishing, starting with a minimum of 50%. This fishing has negatively affected so many while benefitting so few and it must be adjusted. We no longer have the amount of menhaden in our waters and with the loss of these fish, there has been a significant loss of bluefish, striped bass, weakfish, cobia, porpoises, whales and sharks. I rely on bringing home 2-3 meals a day of fish caught to feed my family and with the decrease in menhaden population that has not been attainable in the last few years.
I spent several years saving and planning on starting a 6 pack charter fishing business and have since cancelled those plans because of the decrease in gamefish in our area due to the menhaden overfishing on the east coast.
The decrease has been visible for several years now and this cap should have already been implemented as your studies and comments have shown and admitted to. Why are we waiting until this is too late?
My name is Sean Regan. I live in Breezy Point NY. I am strongly in favor of a minimum of 50% reduction on industrial menhaden fishing. I believe this will have a positive impact on thousands of people outside of the industrial harvesters who rely on menhaden on one way or another for a living to support themselves and their families all along the East Coast. The harvest should be spread evenly across a season and the reduction should meet the ASMFC's ecosystem target.

Management Board, this is my suggestion for the upcoming decisions that need to be made for Addendum II on Atlantic Menhaden.

- **3.1 Chesapeake Bay Reduction Amount**
  - **Sub Option B4 –** a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

- **3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period**
  - **Option B1 –** Even Length & Even Harvest.

- **3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages**
  - **Underage Sub Option 1 –** an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

- **3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision**
  - **Option B –** The Chesapeake Bay Cap will be reviewed at least once every three years.

Categories: Menhaden 2 Auto Replied

Dear Management Board,

As a concerned charter captain, business owner and resource user on the coast of Maine, I believe Atlantic menhaden deserve a 50% chance of not exceeding the ERP fishing target. This means a 40% reduction in TAC, bringing it down to 114,200 metric tons. All of the coastal ecosystems would benefit from this, thus benefiting businesses like my own and coastal economies alike. As I'm sure you all know these are possibly the most important forage species coastwide for so many different species of fish, marine mammals and birds alike. Without healthy menhaden populations we cannot have healthy coastal ecosystems and productive coastal economies. Please manage to the target.

Subject: [External] No menhaden-No Osprey

Categories: Menhaden 2 Auto Replied

I am writing to draw urgent attention to critical ecological shifts observed within the Chesapeake Bay ecosystem, specifically impacting its emblematic wildlife populations. My long-standing engagement with and continuous observation of the Chesapeake Bay, spanning numerous years, offers a grounded perspective on the fluctuating health of its diverse species.

Among these, the Osprey (Pandion haliaetus) serves as a vital bio-indicator and a significant apex predator within the Bay's complex food web. The Bay's abundant marine life historically sustains these magnificent birds. Over the preceding two-year period, my rigorous documentation of Osprey behavior across multiple nesting and foraging sites has yielded deeply concerning findings. Specifically, observations within the South River tributary indicate a pronounced deterioration in Osprey foraging efficacy.

A mere two years prior, these areas thrived with a robust Osprey presence, frequently displaying 8 to 15 individuals engaged in successful, successive hunting dives. In stark contrast, my recent observations this year consistently show only a solitary male Osprey, exhibiting an alarming absence of hunting attempts. While various alternative fish species, including catfish, carp, and snakehead, inhabit these waters, they do not fulfill the specific nutritional requirements of Ospreys. These raptors depend critically on full-sized Menhaden (Brevoortia tyrannus) due to their indispensable high omega-3 fatty acid content, crucial for adult health, breeding success, and the healthy development of their offspring.

While fully cognizant of the economic dimensions associated with Menhaden harvesting, the current intensity and scale of commercial extraction raise profound questions regarding the long-term ecological sustainability and responsible resource stewardship of the Bay. The continued, large-scale depletion of this keystone species threatens irreversible cascading effects throughout the Bay's intricate food web, potentially leading to the loss of biodiversity and compromising the entire ecosystem's resilience. This situation starkly echoes historical precedents of unchecked natural resource exploitation leading to ecological collapse. It is imperative that we critically re-evaluate whether short-term economic gains, particularly those benefiting large-scale commercial fishing entities, should be permitted to override the foundational imperative of preserving our invaluable natural heritage for posterity.

To proactively address these emerging impacts and secure the long-term viability of the Chesapeake Bay's Osprey population, I strongly advocate for the immediate consideration and implementation of evidence-based interventions. Specifically, I propose two actionable strategies:
* Implementation of a temporary, but complete, moratorium on Menhaden fishing within all designated Chesapeake Bay regions for a minimum period of one year.
* As an alternative measure, a significant reduction, by at least 50%, in Menhaden harvesting quotas specifically during the critical initial half of the Osprey nesting season. This measure is designed to

guarantee these birds access to essential nutritional resources during their most vulnerable period of raising young.

As stewards entrusted with the preservation of our natural world, we bear a profound collective responsibility to enact proactive measures safeguarding our invaluable wildlife and irreplaceable natural resources. I earnestly appeal to you to meticulously review the compelling scientific and observational evidence presented, heed the urgent ecological imperative, and act with decisive foresight and unwavering commitment to ensure the enduring health of the Chesapeake Bay for future generations.

Please, I implore you do the right thing.

As a true water person and having lived boated,fished along the waters of our Atlantic Ocean and Barnegat Bays, the lack of and utter disastrous schools of bunker,menhaden or butter fish, call them what you will they are the life line if our bird life (Ospreys) and ocean lives that depend upon an abundance of fish to survive.
The audacity of these fishing(haha) scum fleets and spotter plans is absolutely another incomprehensible action that is allowed (fertilizer and fish oil) by outside countries fleets or our own fleets must be stopped. As someone who spends every weekend and most late afternoons enjoying our spectacular beaches, the lack of Oceanic mammal activity either aerial or from below our Mother Ocean was such a disheartening sight this summer, and this. An only be caused by the over fishing (collecting) of these fisheries, our Oceans are the engines that run this planet and every oceanic mammal, animal and bird species depend on this engine as we all do. This insanity and disdain for our oceans inhabitants must stop, fishing ok but just greedy harvesting , our planet will not survive
Sincerely
John Ward

Please reduce and cap the Chesapeake Bay menhaden reduction harvest. Given the uncertainty around Bay-specific abundance and the importance of menhaden to the Bay ecosystem and predators, a precautionary approach is warranted. I support a substantial reduction in the current cap, along with enforceable seasonal limits to ensure adequate menhaden remain available throughout the year.

I am neutral in this. But as I have been having conversations about the ospreys the all the facts are not being told and the so called decline affecting ospreys. What is being told is the are starving but in fact no autopsy's have been done to prove that information only sightings. As well if you look at research data in the affected areas there is major evidence of forever chemicals at high levels to a point states are asking people to only eat certain amounts of fish and certain species as they have high concentrations of of those chemicals. The chemicals have shown up in fish testing and tissue samples. The areas affected are from the Chesapeake bay mouth to far NE. And that where the high concentrations of these chemicals are being found especially in the New Jersey and Massachusetts area NY as well. There are mapped areas of these chemicals and it is direct relation to the areas that the osprey are showing signs of struggles. Ben Wurst was sent this information today as well Adams many others have been sent the same information. They chose not to show it for certain reasons as you may guess what those reasons are. Again there have been no autopsies performed a on any of those so called starving birds just visual evidence no scientific data what so ever on the death of the fledglings. Thank you for time I think all information should weighed about any resources tk make true informed decisions. Tracy Frost

Categories: Menhaden 2 Auto Replied

Good evening,

I would like to submit comment on the Menhaden coastwide TAC reduction. Based on the latest science and corrected math I strongly suggest that the board reduce the TAC by 50% to give the menhaden a reasonable chance. Thank you.

I have been watching osprey for years and what I've seen over the last several years is devastating. Well established pairs that were known to fledge 3 year after year are struggling to find enough food to fledge 1. For anyone watching them, there is nothing more heartbreaking than to watch the chicks starve to death on the nest. There are many studies that lay the blame on a number of environmental issues, and they do have some impact. But the lack of food is the primarily cause, and we can and must do something to limit the industrial harvesting of menhaden. We must act now to Save Our Osprey.

It seems the only logical solution would be to put a moratorium on fishing Menhaden. If it's not the cause the Osprey nests will continue to fail. If it is the cause maybe limit the amount of Menhaden caught so all can survive on it.

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commissioners,

Friends of the Rappahannock (FOR) is a 501c3 non-profit watershed conservation organization whose mission is to be a voice and active force for a healthy and scenic Rappahannock River.

FOR appreciates the opportunity to submit the following comments and option preferences.

Atlantic menhaden are a keystone species, meaning that they play a major role in holding up the aquatic ecosystem of the the Rappahannock River and Chesapeake Bay.. They are crucial for coastal economies and food webs. These small fish can account for 30% of the diet of striped bass, 33% of the diet for seabirds, and more than 70% of the diet of ospreys. In recent years, the reproductive rates of ospreys who live in areas where they depend on menhaden have hit a new low. According to peer-reviewed research, food stress, particularly due to a lack of menhaden, is driving this productivity crisis.

The Center for Conservation Biology at William & Mary Middle recently released results from 2026 breeding performance results for osprey which found the 2026 breeding season was the worst productivity year ever recorded for osprey in the Chesapeake Bay. Included in the study were areas of the Middle Rappahannock River and Lower Rappahannock River where average productivity was less than 0.2 young/pair.

Given these findings and the current downward trend of striped bass populations we believe a cautionary approach is warranted while studies assessing abundance of menhaden in the Chesapeake Bay are completed.

Accordingly, FOR supports the following options and encourage adoption in Addendum II:
3.1 Bay Cap: Option C1E and C2A
3.2 Bay Cap Distribution: Option B2 (Even Length/Uneven Harvest) and Option B for Quota Period Overages/Underages
3.3 Bay Cap Revisit Provision: Option B (To revisit the Cap every three years)

Respectfully submitted,

Brent Hunsinger

Subject: [External] Menhaden Ocean TAC

Categories: Menhaden 2 Auto Replied

Good Afternoon,

My name is Jonathan Agosta, and I am a recreational angler from New York.

I am writing to urge the ASMFC to reduce the Ocean TAC for menhaden from 180,000 metric tons to no more than 114,000 metric tons. This is the minimum reduction required for a 50 percent chance at a timely stock recovery.

It is worth noting that menhaden is the most important forage species on the east coast of the United States. Every effort should be focused on the protection and recovery of this species, as hundreds of fish, bird, and mammal species rely on menhaden as a prey item.

If this reduction results in an increase to the cost of menhaden as bait, that is an acceptable consequence: the fisheries for which we use menhaden as bait will not exist without a healthy menhaden stock. And the economic fallout that would follow the collapse of those fisheries is orders of magnitude greater than the economic impact of a reduction to the menhaden fishery.

For the aforementioned reasons, I implore the ASMFC to implement AT LEAST the minimum reduction of 66,000 metric tons to the Ocean TAC, and encourage a greater reduction than that.

Sincerely,
Jonathan Agosta

Categories: Menhaden 2 Auto Replied

Atlantic States Marine Fisheries Commission
Menhaden Management Board

Dear Board Members,

The Chesapeake Bay is an important nursery for Menhaden along the Atlantic coast and an essential element of the coastal ecosystem that supports countless marine and avian species.

Scientists have shown that the Menhaden population along the Atlantic coast and in the Chesapeake Bay in particular has declined dramatically in recent years. Wildlife biologists have also made clear that recent declines in the Osprey population in the Chesapeake Bay Area are largely due to the increasing scarcity of this food source that is so essential to countless avian and marine species.

Although there are a variety of reasons for the decline in Menhaden populations, only lowering the cap on the Menhaden harvest will effectively address the issue within a time frame that could give the Osprey and other vulnerable populations a chance to recover.

Please vote in for a 40 percent reduction in the coastwide total allowable catch (TAC).

Sincerely,
Jane Osburn

Subject: [External] Menhaden Ocean TAC

Categories: Menhaden 2 Auto Replied

Good afternoon,

Ahead of the upcoming meeting focused on Menhaden management, I'd like to voice my concerns regarding the Ocean TAC.

In order to have a chance to not exceed the ERP fishing target, the Ocean TAC should not be greater than 114,000 metric tons for Menhaden.

The entire marine ecosystem relies on menhaden to flourish. A decline in the menhaden population will have drastic implications on many other fisheries. **Please protect these fish!**

Best regards,

Martin J Alger

Subject: [External] Menhaden Ocean TAC Adjustments

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission (ASMFC),

I am writing to urge the Commission to take decisive action to protect the ecological integrity of our coastal ecosystems by reducing the Total Allowable Catch (TAC) for Atlantic menhaden by approximately ~40% in order to give the stock a change at recovery.

Menhaden play a critical foundational role in the marine food web. As key forage fish, they sustain an array of economically and ecologically vital species, including striped bass, bluefish, weakfish, marine mammals, and seabirds. Given the ongoing ecological demands on these predator populations, management strategies must prioritize ecosystem health over short-term harvest limits.

Reducing the TAC for Atlantic menhaden is essential to give the stock the greatest chance of meeting and maintaining the ecological target. Adopting a precautionary approach will strengthen coastal food webs, support predator recovery, and foster long-term sustainability for our marine ecosystems and dependent coastal communities.

Thank you for your consideration and commitment to science-based fisheries management.

Sincerely,
--

I support the proposed 40% reduction in menhaden catch. As an avid Delaware recreational fisherman, I have observed a complete lack of the large schools of menhaden that were once common along the Delaware coast. While I recognize there may be multiple factors contributing to this decline, the lack of menhaden I have personally observed in recent years is concerning. A 40% reduction in harvest is a reasonable precaution while we work to better understand the factors affecting menhaden abundance and ensure this important forage fish remains available for the broader marine ecosystem.

Please register my comments on the Atlantic Menhaden. I am in favor of the following:

3.1 Chesapeake Bay Reduction Fishery Cap Amount
Option C1e: To reduce the Chesapeake BayCAP by at least 50 percent in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).
Option C2a: To set the maximum upper limit in any future change at the current level of 51,000mt.

3.2 Chesapeake Bay Cap Distribution
Option B2: To establish three even length quota periods for the Chesapeake Bay Cap, distributing the harvest at 25% in period 1, 25% in period 2, and 50% in period 3.
Option B: Provides any underage of Quota Periods 1 or 2 be rolled into Period 3 of the same fishing year. Any underage in Quota Period 3 would not be reallocated. Any overages would be deducted from the same quota period in the following year.
3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B: Revisit the Chesapeake Bay Cap every 3 years.

Thank you ,

ASMFC Board,

As a native to the east end of Long Island the waters here are my continuous home and refuge. In recent years with the cuts and caps on fishing the return of wildlife has been so abundant and delightful it becomes bliss for us all on the beaches. I've traveled all over the world and I'm so happy to be able to call this place home. But it wouldn't be the same without maintaining the diversity of life in these waters.

Please, I support a 40% cut to approximately 112,100 metric tons for 2027 and 2028.

Let's keep fish in the water for recreational, commercial, and ecological considerations alike. Plain and simple.

Please make the right decision for our coast.

Thank you for your hard work!

Best,
Leo Turpan

To whom it may concern,

Please note my very strong support for the further management of the vital menhaden fishery. Specifically, with respect to the Draft Addendum II to Amendment 3, I support the following positions:
- Section 3.1 - 50% reduction in the current Bay Cap
- Section 3.2.1 - Even length and even harvest, as described in Option B1
- Section 3.2.2 - Rolling underage in Quota Period 1 to Quota Periods 2 & 3, split evenly
- Section 3.3 - Ensuring the Chesapeake Bay Cap will be reviewed at least every three years (Option B)

I fish extensively in the Gulf of Maine as a recreational angler and can attest to the value of menhaden to this fishery. The decline in striped bass population, and the clear reduction in fat content of the GBFT in our local waters, can be directly attributed to the reduction of this vital baitfish. A further reduction in the menhaden population will jeopardize not only the apex stocks in our waters, but the industry built around pursuing them.

As an example of the value of menhaden to our local economies, between Memorial Day and the end of October, I fish approximately 100 days each year. This level of activity equates to approximately 2,000 gallons of marina-purchased gas, $15,000 per year in local boat servicing fees, and over $5,000-10,000 per year in tackle replacement (purchased almost exclusively locally) - conservatively, that equates to over $25,000 per year in direct fishing-related expenditures that go into our local economy. The menhaden underpin all of this activity for me and continued degradation of the stock will only reduce my time on the water, with a corresponding reduction in spending.

I strongly urge the ASFMC to take action to protect this vital resource of our Atlantic States.

Thank you,
-Spencer Hoffman

As a citizen of Maryland, I am deeply concerned that the overharvest of Menhaden is destroying important Maryland fisheries as well as causing a catastrophic crash in the populations of birds, such as Osprey, who feed upon the fish. Overharvesting is unsustainable for Chesapeake fish and bird populations and even for the industry that harvests these fish. It cannot go on.
Please stop the irresponsible destruction of the Menhaden population.

Subject: [External] Public Comment on the 2027–2029 Atlantic Menhaden Coastwide TAC

Categories: Menhaden 2 Auto Replied

To the Atlantic Menhaden Management Board,

I am writing regarding the upcoming decision on the coastwide Atlantic menhaden total allowable catch for 2027–2029.

I urge the Board to adopt a substantial reduction in the coastwide TAC. Specifically, I support reducing the current 186,840 mt TAC by at least 30%, to approximately 130,788 mt, and I encourage the Board to seriously consider a 50% reduction, to approximately 93,420 mt, if supported by the Technical Committee's updated analysis.

The previous 20% reduction from 233,550 mt to 186,840 mt needs to be considered in the context of actual harvest. According to the figures presented in the current management discussion, 2024 harvest was approximately 186,155 mt. Consequently, setting the subsequent TAC at 186,840 mt imposed very little reduction relative to the amount the fishery had actually been removing.

That distinction matters. A reduction relative to a previously authorized TAC is not necessarily equivalent to a reduction in fishing pressure relative to realized harvest.

More importantly, management is now operating with materially different information about Atlantic menhaden productivity following correction of the natural mortality assumptions used in the assessment. When the scientific basis for previous harvest expectations changes, management targets should change with it. Maintaining approximately the same realized removals despite evidence that previous assumptions overestimated stock productivity would not adequately incorporate that uncertainty.

I recognize that Atlantic menhaden management must balance a valuable commercial fishery with the species' ecological role. That is precisely why I believe a meaningful TAC reduction is warranted.

Menhaden are not simply another harvested stock. They are a major forage species linking lower trophic production to striped bass, bluefish, weakfish, coastal sharks, marine mammals, seabirds, and numerous other predators. The ecological reference point framework was an important advancement because it recognized that sustainable management of a forage fish cannot be defined solely by whether the target species itself avoids recruitment overfishing.

There is also reason to consider future changes in fishing pressure rather than managing solely from recent landings. The severe decline of Atlantic herring creates the potential for additional demand for menhaden as bait, particularly in New England. A TAC should therefore provide an actual biological

constraint on removals rather than simply accommodate whatever level of fishing effort and market demand develops beneath it.

My concern is not with eliminating the menhaden fishery. Commercial fisheries require productive and resilient stocks just as recreational fisheries and predators do. Reducing harvest now provides a greater buffer against assessment uncertainty, changing environmental conditions, shifts in fishing effort, and the ecological consequences of removing large quantities of forage.

For those reasons, I support a coastwide TAC reduction of at least 30% and consideration of a 50% reduction based on the Technical Committee's updated analysis. Combined with stronger Chesapeake Bay-specific management, a meaningful coastwide reduction would better reflect the scientific uncertainty now facing this fishery and the unusually important ecological role Atlantic menhaden play along the Atlantic coast.

Thank you for considering my comments.

Sincerely,

Paul Kameen

Subject: [External] Public Comment on Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

To the Atlantic Menhaden Management Board,

I am writing to submit public comment on Draft Addendum II to Amendment 3 of the Atlantic Menhaden Interstate Fishery Management Plan.

I support the following alternatives:

• Section 3.1: Sub-Option B4 — reduce the Chesapeake Bay Cap by 50%, to 25,500 mt.
• Section 3.2.1: Option B1 — establish even-length quota periods with harvest distributed evenly among them.
• Section 3.2.2: Underage Sub-Option 1 — divide an underage from Period 1 evenly between Periods 2 and 3.
• Section 3.3: Option B — require review of the Chesapeake Bay Cap at least once every three years.

I support these measures because the Chesapeake Bay should not be managed simply as a proportional extension of the coastwide menhaden stock. The Bay is an ecologically distinct and exceptionally important nursery and foraging system, and coastwide abundance does not necessarily tell managers whether fishing mortality is being concentrated too heavily in a particular place or time.

This distinction is especially important for menhaden. The ecological consequences of removing a schooling forage species depend not only on annual coastwide removals, but also on where and when those removals occur. A coastwide stock can meet broad biological reference points while still experiencing patterns of harvest that alter local forage availability for predators.

As someone with a fisheries science background and previous research experience with Atlantic striped bass, I am particularly concerned about treating coastwide abundance as sufficient evidence that localized removals are ecologically appropriate. Striped bass and other predators do not experience a coastwide annual TAC; they experience prey availability at the spatial and temporal scales at which they forage.

The recent correction to Atlantic menhaden natural mortality estimates also warrants a precautionary response. When an important model input has resulted in greater estimated productivity than subsequently supported by the assessment, management should meaningfully incorporate that new information rather than allowing historical harvest levels to become the default simply because they were previously permitted.

I therefore support reducing the Bay Cap to 25,500 mt. I also strongly support distributing reduction-fishery harvest evenly across quota periods. A cap alone does little to address localized depletion if a

substantial portion of the allowable harvest can still be concentrated within a few weeks and a relatively small portion of the Bay.

Finally, requiring the Board to revisit the Bay Cap at least every three years is simply good adaptive management. Menhaden abundance, predator populations, environmental conditions, fishing effort, and the science informing management will continue to change. The management framework should be capable of responding accordingly.

Atlantic menhaden are both a commercial resource and a fundamental component of the coastal food web. Management should recognize both roles. I urge the Board to adopt the alternatives above and establish a substantially reduced Chesapeake Bay Cap accompanied by meaningful spatial and temporal safeguards.

Thank you for considering my comments.

Sincerely,

Paul Kameen

To whom it may concern:

As an avid inland water fisherman in the Long Island Sound, I have observed a significantly reduced bunker population during the fishing season. As a result, at least anecdotally, I have also noticed a dramatic decline in the striper fishery, as well as bluefish and Albies. Moreover, as a summer resident in Old Lyme, CT I've observed far fewer Osprey than seems typical. This is highly concerning to me. I understand the increased commercial fishing activity that has been occurring over the last several years off New Jersey and Virginia has had a dramatic effect on the bunker migration north to our waters, which may be a reason for the reduced fish and osprey numbers I typically see. I ask that this situation be evaluated further and considered in the referenced matter.
Thank you for attention to this matter.

Respectfully,
Charles Galante
CT Resident

Subject: [External] Coastal Menhaden TAC

Categories: Menhaden 2 Auto Replied

The menhaden allowance is not just a foraging issue.

Menhaden are filter feeders. Using gill rakers to collect algae and other forms of plankton as they swim, menhaden filter 7 gallons of water per minute. In food-rich environments, they feed by ramming, that is, swimming with their mouths wide open driving water over the gill rakers collecting food. Menhaden can live up to 12 years filtering over 10,000 gallons on a good day.

It's not just about whether menhaden are "overfished" by safe population numbers or foraging availability. It is also about whether industrial fishing of menhaden is leaving the marine environment overburdened with plankton. Excessive algae blooms create deoxygenated zones, the dead zones that kill off everything in the water. A robust menhaden population can help to mitigate these issues.

Preserve the menhaden to preserve the foundations of our marine environment.

Respectfully submitted,

Andy Cain
Carrollton, Virginia

Dear Menhaden Ocean TAC,

As an avid striped bass angler for the past 20 years, I have seen a dramatic reduction in the bunker stock, alongside a noticeable decline in the number of striped bass I catch.

I am writing to express my support for a 40% reduction in the coastwide menhaden TAC, bringing it to approximately 112,100 metric tons for 2027 and 2028.

Sincerely,

Jacob Gettier

Subject: [External] Atlantic Menhaden Draft Addendum II – Public Comment

Categories: Menhaden 2 Auto Replied

I am writing to provide comment on Draft Addendum II to Amendment 3 of the Atlantic Menhaden Fishery Management Plan.

For Section 3.1, I support Sub-Option B4: a 50% reduction in the Chesapeake Bay Reduction Fishery Cap, reducing the current 51,000-metric-ton cap to 25,500 metric tons.

For Section 3.2.1, I support Option B1, Even Length and Even Harvest, to distribute reduction harvest more evenly throughout the fishing season.

For Section 3.2.2, I support Underage Sub-Option 1, under which an underage from Quota Period 1 would be divided evenly and carried into Quota Periods 2 and 3.

For Section 3.3, I support Option B, requiring the Chesapeake Bay Cap to be reviewed at least once every three years.

I also support keeping the Chesapeake Bay Cap independent from the coastwide TAC rather than automatically linking the two. The Chesapeake Bay has its own ecological conditions, patterns of fishing effort, and importance as forage habitat. I believe retaining a fixed, independently managed Bay Cap allows the Board to respond specifically to conditions within the Bay.

Taken together, I support these measures because they would reduce the overall Bay Cap while also addressing the concentration of reduction-fishery harvest during relatively short portions of the season. Menhaden are an important forage species for striped bass and numerous other predators, and I believe management should account for that broader ecological role.

Thank you for considering my comments.

Categories: Menhaden 2 Auto Replied

I am writing regarding the Atlantic menhaden coastwide Total Allowable Catch for 2027 and 2028.

I support reducing the coastwide TAC by approximately 40%, to roughly 112,100 metric tons.

Menhaden are an important forage species throughout the Atlantic ecosystem, supporting striped bass, bluefish, tuna, marine mammals, seabirds, and other predators. I believe management of this fishery should give substantial consideration to menhaden's ecological role and to the Ecological Reference Points established for the stock.

I am particularly concerned by the projections presented for the current 186,840-metric-ton TAC and the risk of exceeding the ecological fishing target. I believe a reduction to approximately 112,100 metric tons represents an appropriate precautionary response to that information while leaving substantially more menhaden in the ecosystem.

I also believe the coastwide TAC and the Chesapeake Bay Cap should be treated as separate management decisions. Addressing harvest within the Chesapeake Bay alone does not address coastwide fishing pressure or the ecological importance of menhaden throughout their range.

For these reasons, I support setting the 2027 and 2028 coastwide Atlantic menhaden TAC at approximately 112,100 metric tons.

Thank you for considering my comments.

Hello,

I am writing to express my strong support for a 40% reduction in the menhaden ocean TAC.

A series of significant management errors and excessive harvest practices have contributed to the depletion of one of the Atlantic's most important forage fish. Menhaden play a foundational role in the coastal ecosystem, and continued overexploitation threatens not only the species itself but also the many fish, birds, and marine mammals that depend on it.

It is time for fishery managers and stakeholders to acknowledge these mistakes and take meaningful corrective action. A substantial reduction in harvest is a necessary step toward protecting this resource for future generations.

Thank you for your time and consideration.

Respectfully,
Tim Begin

Hello,

I support the 40% reduction to approximately 112,100 metric tons for 2027-2028. I believe this is a matter of urgency as I have seen first hand the devastating results to Osprey not having enough food over this past summer. Every nest that I track saw babies that did not make it due to lack of food. I have also spoken to people who fish the waters off the coast of Connecticut on Long Island Sound and they have also noted a big decrease in Menhaden resulting in less bass.

Please consider this reduction.

Regards,
Susan Cannarella

Subject: [External] Public Comment on Menhaden Draft Addendum

Categories: Menhaden 2 Auto Replied

I have previously submitted my comments regarding the reduction of the menhaden quota in the Chesapeake Bay for the reduction industry. I would also like to comment on the proposal to reduce the coast wide total allowable catch. I am a NJ resident working for a tackle shop as well as a mate on a charter boat. The decline in the menhaden population over the past 5 years along the NJ coast is undeniable and those that remain are not full-size adult fish. The current 186,000 + TAC is unsustainable to this species and the wildlife that depend on it and I urge you to consider a reduction of no less than 40% to this quota for the 2027 - 2029 seasons with the provision to revisit the status of the biomass after that. Failure to act immediately only risks further damage to the birds, fish and marine mammals that depend on menhaden for spawning success and survival.

Subject: [External] Comments - Menhaden Ocean TAC

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic Menhaden Management Board,

I am writing to ask the Board to establish the **2027 and 2028 coastwide Atlantic menhaden TAC at approximately 112,100 metric tons, representing a 40% reduction from the current 186,840-metric-ton TAC.**

I am a Maine-based saltwater fly-fishing guide, and menhaden are directly connected to the fishery I spend my life on. I see their importance every season—not only to striped bass and other gamefish, but to the entire coastal food web.

The recent science makes this an especially important decision. Preliminary projections presented by the ASMFC's Menhaden Technical Committee on September 28 indicate that the current 186,840-metric-ton TAC carries a **99.5% probability of exceeding the ecological fishing mortality target** in each projected year. Those projections showed that a TAC of 114,200 metric tons would reduce that risk to 50%, while 110,200 metric tons would reduce it to 40%. A TAC of approximately **112,100 metric tons** represents a meaningful 40% reduction and moves management substantially closer to that ecological target.

I understand that the coastwide stock is not currently classified as overfished and that overfishing is not occurring under the stock-status framework. But I don't believe we should wait for the stock to reach a crisis point before acting. The ecological reference points exist specifically to account for menhaden's role as a forage species, and the current projections indicate an extraordinarily high risk of exceeding the associated target at the existing TAC.

As a guide, I see menhaden as much more than a number in a quota table. They are the fuel that supports the striped bass, bluefish, tuna, whales, birds, and countless other predators that make our coastal waters what they are. They also support the recreational fisheries and coastal businesses that depend on those predators.

I respectfully ask the Board to set the 2027/2028 coast-wide TAC at approximately 112,100 metric tons—a 40% reduction from the current TAC.

I believe leaving more menhaden in the water is an investment in the resilience of the entire ecosystem and in the fisheries and coastal communities that depend upon it.

Thank you for considering my comments.

Respectfully,

Capt. Ben Whalley

Subject: [External] Atlantic Menhaden Draft Addendum II — Chesapeake Bay Cap

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic Menhaden Management Board,

I am writing to voice my support for the following management options for Atlantic Menhaden moving forward.

For Issue 3.1, Chesapeake Bay Reduction Amount, I support Sub-Option B4 — a 50% reduction in the current Bay Cap, establishing a fixed cap of 25,500 metric tons.

I also support **Option B1 for Issue 3.2.1 — Even Length & Even Harvest**, dividing the Bay Cap into three equal quota periods with equal harvest allocations. For **Issue 3.2.2, I support Underage Sub-Option 1**, in which an underage from Quota Period 1 is split evenly between Quota Periods 2 and 3. Finally, for **Issue 3.3, I support Option B**, requiring the Chesapeake Bay Cap to be reviewed at least once every three years.

I am a Maine-based saltwater fly-fishing guide, and I make my living on the coastal ecosystem that depends on abundant forage. From my perspective on the water, menhaden aren't simply another commercially harvested species. They are the foundation of the food web supporting striped bass, bluefish, tuna, whales, ospreys, and countless other predators.

I particularly support keeping the Bay Cap **fixed at 25,500 metric tons rather than tying it directly to the coastwide TAC**. Chesapeake Bay is a unique and critically important ecosystem, and I don't believe a coastwide assessment should automatically determine how many menhaden can be removed from this particular system. ASMFC acknowledges that its current assessment does not provide stock-status information at the smaller Chesapeake Bay scale.

Reducing the cap is important, but so is **when and how those fish are removed**. Spreading harvest evenly across the season would reduce the concentration of fishing effort that has developed during portions of the summer. A three-year review would also provide an opportunity to evaluate whether these measures are accomplishing their intended purpose as additional information becomes available.

As someone who spends hundreds of days on the water, I want to see a management approach that leaves enough menhaden in the ecosystem to support the fisheries, wildlife, and coastal communities that depend on them.

I respectfully ask the Board to adopt **Sub-Option B4, Option B1, Underage Sub-Option 1, and Option B** as outlined above.

Thank you for considering my comments and for your work managing this critically important resource.

Respectfully,

Capt. Ben Whalley

Subject: [External] Draft Addendum II for Atlantic Menhaden

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

I am writing to share my concern about the future of the menhaden (bunker) population and the fishery it supports.

Over the past three years most significantly but a consistent decline for 10 years plus, I have observed a dramatic decline in menhaden throughout the Connecticut River, Western Long Island Sound, South Shore of Long Island and surrounding waters. Industrial menhaden harvest farther south, particularly in Virginia and New Jersey, is an important part of the discussion because removing large numbers of menhaden (bunker) before they migrate north can reduce the forage available to our waters.

Bunker is a critical forage species for striped bass, bluefish, and other marine life, and their abundance has significant implications for recreational fishermen, guides, charter captains, tackle shops, marinas, and coastal communities.

I encourage ASMFC to carefully consider the impacts of industrial menhaden harvest and the need to maintain a healthy forage base for the future.

Thank you for considering the observations and concerns of recreational fishermen and coastal communities as you consider Draft Addendum II for Atlantic Menhaden.

Sincerely,

David S. Cingari

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

To the Atlantic States Marine Fisheries Commission,
I am writing to express my strong support for increasing protections for Atlantic menhaden. As a critical forage fish, menhaden form the foundational base of our coastal marine ecosystem. They are a vital food source for key predators, including striped bass, bluefish, ospreys, and marine mammals.
I am deeply concerned by noticeable signs of a shrinking menhaden population and the resulting strain on the wildlife that depends on them. To safeguard the long-term health of our coastal waters, we must prioritize ecosystem-based management over maximizing industrial yields.
I urge the Commission to take a precautionary approach by implementing a meaningful reduction in the coastwide harvest limits and enacting a strict reduction cap on the industrial harvest. Protecting this irreplaceable forage species now is essential to ensuring the resilience of our shared marine ecosystems and coastal economies.
Thank you for your time and your dedication to managing our public marine resources.
Sincerely,
Raymond West

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission (ASMFC),

I am writing today as a passionate wildlife advocate and resident to express my support for the highest protective management measure under Draft Addendum II. Specifically, I encourage the Commission to select Option B4 which implements a 50% reduction in the Chesapeake Bay reduction fishery cap, lowering it to 25,500 metric tons. I support the establishment of seasonal quota periods to take away the severe, concentrated industrial harvest that occurs during critical wildlife breeding seasons.

Atlantic menhaden are a critical part of the Chesapeake Bay ecosystem. Our local wildlife is currently sending us a clear sign that the current cap is unsustainably high. Forage depletion has led to an unprecedented ecological crisis for local predator populations. Recent research from the 2026 nesting season shows that osprey reproduction rates have plummeted to near-zero levels in many parts of the Bay, with widespread chick starvation directly linked to a lack of menhaden. Bald eagles, loons, gannets, whales, and dolphins all depend on robust menhaden schools to thrive.

Allowing a single industrial entity to extract over 100 million pounds of these essential fish annually from a concentrated nursery area like the Chesapeake Bay undermines ecosystem-based fisheries management.

To protect the food web that sustains the Bay's incredible biodiversity, please pass the 50% cap reduction (Option B4) and instate strict seasonal quota splitting to distribute and minimize localized depletion.

Thank you for your time and your dedication to protecting our shared marine resources.

Sincerely,

Amanda Lietuvnikas
Manassas, VA

Categories: Menhaden 2 Auto Replied

Hello, I support the following options for the Chesapeake Bay Cap:

3.1 Chesapeake Bay Reduction Amount
Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
Option B1 – Even Length & Even Harvest.

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

Thank you for taking my comment.

Subject: [External] Atlantic Menhaden Draft Addendum II Public Comment

Categories: Menhaden 2 Auto Replied

Hi,

I hope this email finds you well. I wanted to express my concern about the ecosystem in the Chesapeake Bay currently being threatened by the overfishing of menhaden. I believe that reducing the fishery cap by up to 50% would be a great start to supporting this ecosystem and preventing it from collapsing. Many animals that live in the Chesapeake Bay, like the Ospreys, rely heavily on a diet consisting exclusively of Atlantic menhaden.

However, the Ospreys have been suffering from a food shortage in the bay and on the East Coast as a whole due to the overfishing of menhaden. This has resulted in nearly 3 years or so of Osprey chicks starving to death due to the limited amount of menhaden, which is causing the Osprey populations on the East Coast to plummet further than they've ever been previously, even when compared to their low numbers caused by DDT pesticide poisoning between the 1940s and 1970s.

This is especially concerning given that in Illinois, Osprey chicks from the East Coast are collected and reintroduced as part of Illinois' Osprey Hacking Project. However, the food shortage resulting in a low number of Osprey chicks has been negatively impacting the recovery program. The importance of maintaining a healthy and thriving Osprey population along the East Coast, including the Chesapeake Bay area, is crucial in order to help Osprey populations continue to rebound in other parts of the country.

I kindly ask the Atlantic States Marine Fisheries Commission to consider modifying the Chesapeake Bay Reduction Fishery Cap to reduce the fishing of menhaden to up to 50%.

Thank you for your consideration,

Joseph Bruno

Subject: [External] Limit on menhaden fishing

Categories: Menhaden 2 Auto Replied

I am concerned about the decline of the coastal osprey population. I read about this problem and am asking the commission to work to drastically reduce the number of menhaden allowed for commercial fishing. Ospreys rely on these fish, and without this food source, they cannot survive. Please consider how you can help these amazing birds survive. Thank you ;

Subject: [External] Menhaden TAC

Categories: Menhaden 2 Auto Replied

Good Afternoon,

My name is Capt. Tom Kosinski and I am a fly and light tackle fishing guide on the northern New Jersey coast and I would like to provide my input for the upcoming decisions on the management of Menhaden.

I support the following selected alternatives for the Chesapeake Bay Cap, as ecologically and socioeconomically appropriate, to inform effective management actions, reduce the risk of overfishing, and promote resilient futures for the resource and its communities.

- 3.1 Chesapeake Bay Reduction Amount
  - Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

- 3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
  - Option B1 – Even Length & Even Harvest.

- 3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
  - Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

- 3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
  - Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

Regarding the coastwide TAC, itmust be reduced by at least 30%, from the current 186,840mt to 130,788 mt. Ideally, the coastwide TAC should be reduced by 50%, lowering the operating TAC to 94,420 mt. These are the only options to ensure the coastwide commercial Atlantic Menhaden fishery operates at a capacity that does not carry a 100% probability of overfishing.

Paired with the appropriate management actions for the Bay outlined in Draft Addendum II, these options for the coastwide fishery offer the best path forward for resilient futures for Atlantic Menhaden.

Best,
Capt. Tom Kosinski
Sandy Hook Outfitters

To whom it may concern,
My name is Dave Guyette. I have been fishing the Connecticut Long Island sound for many many years. Four or five years ago I was seeing large schools of Menhaden At the mouth of the Connecticut river and areas surrounding it. Both last year and this year I have seen few if any Menhaden And believe it is severely affecting the striped Bass population. Furthermore, I believe there should be a substantial reduction in commercial harvesting of these critical fish.
Thank you in advance for your attention to this important matter
Thank you

David Guyette

Subject: [External] Menhaden Draft Addendum II: Support for a 50% Reduction in the Chesapeake Bay Menhaden Harvest Cap (Draft Addendum II)

Categories: Menhaden 2 Auto Replied

I am writing in support of the 50% reduction to the Chesapeake Bay menhaden reduction fishery cap in Draft Addendum II.

I live on a tidal creek on Kent Island, Maryland, and for 5 years I have watched the ospreys here almost every day, most mornings from a kayak. I follow twelve nests along this stretch of shoreline. A healthy population needs roughly one fledged chick per nest each year. Last year my twelve nests fledged three chicks, and the year before that, three again. I cannot prove what caused those numbers, but I can tell you what I have seen this season: 2026 was the worst with only 2 chicks to fledging. Out of 12 nests, that's only 0.17 reproduction rate whereas 1.0 is the minimum for population replenishment!

One of the two chicks was born right in front of my house. The male of this nest has been feeding his mate and chick since late spring. Large menhaden have been scarce, so he has been diving again and again for fish three or four inches long, which are much harder to grip. On days he couldn't find enough, he brought home white perch or spot instead. Some days he made eight trips. Late in the season, on August 30th, I watched him dive and come up empty, something I had almost never seen from him. Nearby, on the morning of September 4th, another male made six dives in a row and was unsuccessful. That pair has not raised a chick in three years.

Earlier this summer, on July 3d, I also watched about thirty bottlenose dolphins move into a creek only six feet deep at high tide, well beyond where I would expect them. I don't know why they were there, but they were clearly working hard to find food.

I am not a scientist, and I don't claim that menhaden alone explain these observations. But ospreys, dolphins and striped bass all depend on the same small fish, and the Bay is one of the places where young menhaden grow up. When I see the animals at the top of the food web working this hard for so little, I think caution is warranted.

I urge the Commission to adopt the 50% reduction in the Bay cap, so that enough menhaden remain in the water for the wildlife that depends on them.

Respectfully,

Benoit Cossart

Stevensville, Maryland

Subject: [External] ASMFC Annual Meeting, Menhaden Board

Categories: Menhaden 2 Auto Replied

Hi There,

I'm a Norfolk, Virginia native who grew up fishing and crabbing on the Chesapeake Bay. I now live with my family in Boston, where I stay active in the summers fishing for Striped Bass. I'm also involved as an investor and advisor with several "blue economy" businesses who employ hard working people that help us share in the benefits of the ocean.

Like many, I'm deeply concerned by the growing evidence of a major environmental catastrophe in the Bay, driven by the Menhaden reduction fishery in Reedville. The impacts on Osprey are obvious to all - and if the birds are impacted, then surely the harder-to-observe species under the water are also suffering.

I want to urge you to put a complete stop to the reduction fishery in the Chesapeake, effective immediately, in order to provide wildlife an opportunity to recover while research continues on the localized impacts of the Menhaden reduction fishery.

I don't say this lightly - I'm well aware of the jobs at risk of a moratorium, and I know and love many working watermen/women who make an honest living on the water. But clearly the science-based processes that are supposed to protect our watersheds are either a) too slow to keep pace with today's industrialized fishing practices, or b) have been co-opted by Omega Protein and affiliated lobbyists to make it impossible for the research to proceed at the necessary pace. If nothing else, imposing real business costs on Omega Protein will create the urgency and financial incentive necessary to invest in the scientific work that should have been completed years ago when the impacts of the Menhaden fishery was first recognized.

Your organization helped demonstrate, years ago, that smart conservation practices could make a great impact, provided they are grounded in solid research and patient implementation. Please step up at this critical moment to regain the trust of the public and protect one of the most foundational species in our waters.

Teddy Rice
Boston, MA

Subject: [External] Public Comment - Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Mr. Boyle, ASMFC Board Members, LWFC Members, and Public Officials,

I write to you today with grave concern for the Atlantic and Chesapeake Bay Commercial Menhaden fishery. Recent findings confirm abundance is about 37% lower than assumed, and consequently these revisions suggest recent overfishing by 275,000,000+ pounds per year. I have a hard time reconciling this reality with the constant use of words like “precautionary” and “proactive” being used throughout the ASMFC document calling for public comment on this issue. I’m happy to cover the cost of a dictionary to send to the Commission, as precautionary measures would have not resulted in over-harvest by over a quarter of a billion pounds every year. The Precautionary Principle dictates that in situations where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation. The ASMFC has made such inaction their trademark, constantly voting for inaction with the justification of waiting for new data, only to push the can down the road at the next opportunity for action with the same justification. Your constituents are tired. Just look at the striped bass population that is about to collapse, with no recruitment in the last 8 years, and excruciatingly slow management that will only do the right thing when all other options are exhausted and no fish remain. Or the fact that some proposed reductions put forth for both menhaden and striped bass do not actually reduce the overall harvest when accounting for the fact that the quota has not been reached in recent years. Enough.

Menhaden support more than international corporations making cheap animal feed and supplements. They prop up all of the Atlantic coast’s most important and charismatic species, from eagles and osprey to whales, sharks, and dolphins. They filter-feed and regulate planktonic communities that are the foundation of all marine life. They support incredible recreational fisheries that engage millions of stakeholders who spend billions of dollars on their local economies. While I am sympathetic to the *dozens* of commercial fishermen who may have their jobs impacted by these proposed changes, I encourage you to think of the downstream ways in which menhaden produce economic and intrinsic value, and acknowledge that commercial sale of menhaden does not equate to all the indirect value they provide to the ecosystems themselves, coastal culture, and the recreational fishing economy.

My thoughts on proposed regulations are as follows:

3.1 Chesapeake Bay Reduction Amount
Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
Option B1 – Even Length & Even Harvest.

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

It’s easy to reduce harvest from un-achievable quotas to the actual catch so we can pat ourselves on the back for a cheap conservation win and protect non-existent, theoretical fish. It’s hard to act in the best interest of the resource rather than just the industry, but that’s your job. Do your job.

Subject: [External] Atlantic Menhaden Draft Addendum II Please reduce the limit of menhaden allowed to be caught in the Chesapeake Bay

Categories: Menhaden 2 Auto Replied

I am writing to express my opinion on the calamitous results of overfishing of menhaden within the Chesapeake Bay by Omega Protein in Reedville Va. I live in Reedville. I see these massive industrial ships bringing in their menhaden catch every day.

Some days I see 6-8 ships come into Reedville loaded with millions of fish. I have witnessed the effects this overfishing has had on the local osprey population over the years. They are not reproducing or the chicks that are born literally starve to death. I have seen local wildlife rescue personnel come and try to help the osprey chicks but they tell us that the level of starvation has already passed critical and the birds die within a few days. The osprey nest in front of our house has not produced viable chicks for three seasons in a row now.

It is rather obvious how much other species have also been affected by the loss of menhaden. Rockfish, redfish, dolphins, cobia and crabs are also much less prevalent than I've witnessed over the past 11 years here in Reedville. The statistics show there is an entire economy of other businesses throughout Virginia and Maryland who rely on a healthy menhaden population and their combined value to the economy far exceeds Omega Protein's value to a relatively fewer number of working people. The lobbying efforts and the blind loyalty of our politicians is detrimental to a much larger electorate than just the local employee numbers.

And let's be clear, while plant manager Mr. Diehl cries about how Omega's employees will be affected by a reduction in a limit of menhaden inside the bay, I am not advocating for the closure of the fish reduction factory. I am calling for a large reduction in the amount of fish Omega is allowed to take from within the Chesapeake Bay. They can continue to fish in the ocean. Allow the Bay to recover for a period of years and then reevaluate. Omega will catch their limit. They may have to work harder to get it but the immense size and scale of the fishing fleet will be able to continue to make them profitable. Please reduce the limit of menhaden allowed to be caught in the Chesapeake Bay.

Sincerely,

Thomas Gritt

Reedville, Va.

Gentlemen:

My name is Richard Seifert and I am an active surf and boat fisherman in Long Island Sound and Rhode Island. I have serious concerns about the over fishing commercially of the Atlantic Menhaden, and the impact on the marine environment resulting in poor forage for Striped Bass and bluefish, as well as severe impact on the Osprey young and chick rearing success. My personal experience is the population of Menhaden has been significantly reduced, causing both striped bass and other foragers to try to supplement with other species for their dietary needs.

I am sure you know the details of this longstanding issue, and I am praying you will act in the best interests of conservation and science in addressing the commercial quotas on these important baitfish for the region.

Thank you,

Richard F Seifert

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic Menhaden Management Board,

My name is Eric Nordquist from West Hartford, Connecticut. As a recreational fisherman who fishes out of Essex, CT, throughout Long Island Sound and south of Montauk, I am writing to provide public comment on Draft Addendum II regarding the Chesapeake Bay reduction fishery cap, and to address the upcoming 2027–2029 coastwide catch specifications.

A healthy menhaden fishery is essential for a balanced marine ecosystem. When this balance is disrupted, the natural order is interrupted, and abnormal species behaviors take over. Over my time on the water, I have observed that the menhaden population has become very sparse. This lack of forage has reduced striped bass populations in their typical locations, driving them into heavily contested areas like Block Island. In turn, this unnatural concentration has driven an overpopulation of sharks in those waters. Beyond the ecological impacts, recreational fishing is a vital hobby that improves personal health and directly supports the real estate market in our coastal areas.

Because menhaden are the bedrock of the Atlantic coastal food web, I strongly support a precautionary approach to the localized reduction fishery. For Draft Addendum II, I formally support the following management options:

- **Section 3.1, Sub Option B4:** Reduce the Chesapeake Bay reduction-fishery cap by 50%, lowering it to 25,500 metric tons.
- **Section 3.2.1, Option B1:** Establish roughly equal-length seasonal quota periods with the harvest distributed evenly among them to prevent localized depletion during critical feeding times.
- **Section 3.2.2, Underage Sub Option 1:** Split any unused first-period quota equally between the second and third periods.
- **Section 3.3, Option B:** Establish a formal review of the Bay cap at least once every three years to remain responsive to changing conditions.

Crucially, I urge the Board to manage the Chesapeake Bay cap independently. It should be based strictly on localized ecological conditions and nursery forage needs, rather than being automatically linked to the coastwide quota.

Separately, I ask that the Board apply this portion of my comment to the separate decision regarding the upcoming 2027–2029 coastwide catch specifications. For the next three-year period, I support at least a 30% reduction from the 2026 coastwide total allowable catch of 186,840 metric tons, with a strong preference for a 50% reduction.

When evaluating these catch limits, management must recognize the critical distinction between exceeding an ecological fishing-mortality target and exceeding a formal overfishing threshold. Even if the menhaden stock is not currently exceeding the formal overfishing threshold, pushing past the ecological target removes too much forage from the water, directly starving the predators that rely on them.

Protecting forage fish is an economic and environmental necessity. Both commercial and recreational fishing communities depend entirely on a healthy, balanced resource to survive. When the forage base collapses, fishing opportunities evaporate, and the coastal businesses and real estate markets that rely on our fisheries suffer the consequences.

Thank you for your time, your service to our marine resources, and for considering my comments.

Eric Nordquist
West Hartford, CT

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle and Members of the Atlantic Menhaden Management Board,

My name is Matthew Robertson. I live in Ellington, Connecticut, and fish recreationally along the Connecticut coastline, including the Connecticut River. I am writing to support stronger protections for Atlantic menhaden through Draft Addendum II and the upcoming coastwide catch decision.

Fishing is a big part of my life. I put significant time and money into my boat, equipment, and trips, and I want my children to have healthy fisheries to enjoy as they grow up. That requires protecting the forage fish that help support the entire system. Menhaden have value in the water, and that value needs to carry real weight in these decisions.

For Draft Addendum II, I support the following:

- **Section 3.1, Sub Option B4:** Reduce the Chesapeake Bay reduction-fishery cap by 50%, to 25,500 metric tons.
- **Section 3.2.1, Option B1:** Establish periods of roughly equal length with harvest distributed evenly among them.
- **Section 3.2.2, Underage Sub Option 1:** Divide unused first-period quota equally between the second and third periods.
- **Section 3.3, Option B:** Review the Bay cap at least once every three years.

I support managing the Bay cap independently, based on conditions and forage needs within the Chesapeake, rather than automatically linking it to changes in the coastwide quota. An increase in the coastwide quota should not automatically authorize more harvest within the Bay.

Separately, for the 2027–2029 coastwide specifications, I support at least a 30% reduction from the current 186,840-metric-ton total allowable catch, with a preference for a 50% reduction. Please include this portion of my comment in the Board's consideration of those specifications.

The revised assessment gives managers good reason to act conservatively. ASMFC has explained that the 2026 catch limit is still projected to exceed the ecological fishing-mortality target. I want management decisions aimed at meeting that target and providing adequate forage for predators.

I recognize that commercial fishermen and processing workers depend on this resource. Recreational fishermen, charter captains, tackle shops, marinas, and other coastal businesses also have a stake in its future. The economic discussion should account for all of them, including the long-term cost of diminished fishing opportunities.

From my perspective, protecting menhaden in the Chesapeake and protecting them along the rest of the coast need to happen together. Reducing pressure in one place while allowing it to increase elsewhere would leave the larger concern unresolved.

Please adopt meaningful reductions, spread Bay harvest more evenly through the season, and make protecting forage abundance a clear management priority. I want my children to inherit fisheries worth investing their time in, just as I have.

Thank you for considering my comments.

Matthew Robertson
Ellington, Connecticut

Subject: [External] Menhaden in decline.....save our forage fish

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

I am writing to share my concern about the future of the menhaden (bunker) population and the fishery it supports.

Over the past three years most significantly but a consistent decline for 10 years plus, I have observed a dramatic decline in menhaden throughout the Connecticut River, Western Long Island Sound, South Shore of Long Island and surrounding waters. Industrial menhaden harvest farther south, particularly in Virginia and New Jersey, is an important part of the discussion because removing large numbers of menhaden (bunker) before they migrate north can reduce the forage available to our waters.

Bunker is a critical forage species for striped bass, bluefish, and other marine life, and their abundance has significant implications for recreational fishermen, guides, charter captains, tackle shops, marinas, and coastal communities.

I encourage ASMFC to carefully consider the impacts of industrial menhaden harvest and the need to maintain a healthy forage base for the future.

Thank you for considering the observations and concerns of recreational fishermen and coastal communities as you consider Draft Addendum II for Atlantic Menhaden.

Sincerely,

Captain Lou Cavaliere

Subject: [External] Atlantic Menhaden Draft Addendum

Categories: Menhaden 2 Auto Replied

I am in support the Atlantic Menhaden Draft Addendum. In addition, I support a total moratorium on the harvesting of menhaden until the study of that fish population is completed by the College of William and Mary in VA, and the fish levels return to normal. Then, a reduction of the harvest could be imposed that would sustain a desirable menhaden population.

When a moratorium on catching rockfish in the Chesapeake Bay was in effect in the past, the rockfish population increased enough to resume recreational sport-fishing with enforced restrictions. Folks today may have forgotten the loss of the sardines, and the canning industries they supported, due to over-harvesting. And generations ago, the once-abundant Atlantic Cod almost vanished, due to over-fishing.

If a total ban cannot be imposed, then a 50% harvest limit should be required, with spacing to allow times for fish-spawning. It's better than ignoring the crises and doing nothing. Scientists have learned so much more about fish life-cycles and spawning seasons. Why can't we put this information into use to keep fish numbers up to par?

I have been living on a tidal/freshwater estuary of the Chesapeake Bay for over 35 years. During this time I witnessed the return of a pair of ospreys that build a nest on my property and raise fledglings each year. This summer, there were no fledglings. The parent birds have always depended on menhaden as a source of food for their offspring. And now, those fish have almost disappeared here in the upper Bay. Next year, there may be no ospreys. What's next?

We must take action to prevent this huge threat to our environment. Please, keep menhaden harvesting under tighter control.

Sincerely,
Clara L. Gouin

Subject: [External] Atlantic menhaden

Categories: Menhaden 2 Auto Replied

Dears Sirs,

In years past I have seen menhaden crowding into the rivers and streams I fish on. They were very easy to catch with a weighted treble hook, and use for bait on later trips for striped bass and bluefish. This year, the numbers of menhaden seen are very reduced. As are the bluefish and stripers. I believe this loss of forage food is having an impact on the population of fish that so many marinas, tackle shops, and boat owners depend on to make their fishing trips worthwhile, and worth the expense of owning and running a boat. Please protect the menhaden to bring their numbers back to what they were just a few years ago.

Sincerely,

Gary Wilson

Categories: Menhaden 2 Auto Replied

While I am not a very active sport fisherman, I am involved with several non-profit environmental organizations. As someone who is in and around the Bay and tributary rivers, I have seen a dire lack of Osprey nesting and reproduction. It is worse than last year by far. When visiting the Atlantic coast in Ocean City MD, I did not see the usual purplish schooling of Menhaden. When conducting seine net surveys in the Magothy River, we did see a good amount of very small juvenile Menhaden, but none at all of any larger size. My brother lives on the shore of East Point near Onancock VA, and has also seen a severe lack of Osprey nesting and reproduction. We must not allow the decimation of the Osprey and Menhaden populations.

Thank you,
Brad Knopf

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Osprey populations are falling rapidly in specific areas along the East Coast where menhaden are probably unsustainably fished.

Because osprey return from South America to the same areas where they hatched and were raised, fish abundance in those same areas needs to be able to support the returning osprey and their young. When these birds of prey return to find inadequate stocks of fish to feed on, their health suffers, their egg-laying fails, and any chicks that do hatch are left to starve.

The effects of global warming, whatever its causes, have now disrupted the once-coordinated timing of menhaden abundance and the ospreys' return from their winter homes.

The clear effects of humans on the environment in which other creatures have to survive gives us the responsibility to act when our behavior puts other species at risk.

The obvious solution is to reduce fishing of menhaden for at least several years as per, for example, the Virginia Saltwater Sports Fishing Association recommends.

Menhaden fishing needs to be limited and limits revisited every 3-5 years.

Concerned former Chesapeake Bay area resident

Subject: [External] Menhaden commercial fishing is hurting our local fishery

Categories: Menhaden 2 Auto Replied

Hello,

As a fisher in Connecticut, My fellow Fisher's and bait shops have Seen a significant decline in fish in our Local waters, especially over the past 3 years.

We have many local experts that speak at our fishing club from Ct DEEP and other marine biologists. They are pointing to the commercial harvesting of menhaden south of Ct which significantly Reduces the amount of bait fish that make it to Long Island sound. Hence, reducing the amount of striped bass and other fish that consume menhaden.

Is it possible to find a better balance to allow commercial fishers to harvest menhaden at a lower volume so that that it is not detrimental to other fisheries along the north east coast?

Please consider modifying the amount of fish commercial fishers can take so that It doesn't ruin sport fishing for New England and other communities.

Thank you,
Alice Mulqueen

Subject: [External] Atlantic Menhaden Draft Addendum II and 2027-2029 Catch Limits

Categories: Menhaden 2 Auto Replied

I've been surf fishing for 60 years along the New Jersey coast from Sandy Hook to Island Beach State Park. When we retired we deliberately bought a house within an easy drive of Sandy Hook so we could enjoy the beach more often. Never in my life have I seen so many menhaden from shore as in 2023-2024. Along with the mossbunker came dolphins, ospreys and even whales easily visible from shore. I joined hundreds of excited surf fishermen in the fall for striped bass fishing that exceeded my wildest dreams. All of which made the scarcity of bunker, ospreys and striped bass in 2025-2026 starkly noticeable.

In retirement I read more about ocean fisheries and attended local lectures given through our excellent Monmouth County Park system. Park naturalists said the unusual prevalence of bunkers in 2023-2024 was due to regulation of the catch as well as improving water quality. The information obtained regarding the linkage between menhaden and other species confirms my own life experiences.

I am extremely concerned that bunkers are being harvested for such nonessential uses as fertilizer and that a single company dominates the harvest. This activity should be compared to the recreational fishing industry. Try visiting the Jersey shore in October and November if the bass are running and you can watch hundreds of surf fishermen along the coast, many from out of state. Visit the local tackle shops and look at the prices of lures and tackle. Shops are typically sold out of hot lures. Recreational fishing along the Jersey shore is a significant industry that is dependent on bass following baitfish like menhaden. Careful regulation of the bunker catch should be instituted.

Cut the overall harvest of mossbunker along the coast!

Reduce the Chesapeake Bay harvest by at least 50% spread evenly throughout the season!

Bob Markow, NJ surf fisherman

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

As a CT and RI shoreline fisherman for many years, I can say without hesitation that I've never seen such a rapid decline in the catch rate of Striped bass and Bluefish, both from shore and from boat, on the many charter trips I book throughout the season. I log every trip and the species catch and release numbers, all of which have steadily declined, especially the past three years. This year has been the worst by far and I will very likely book less trips next season.

Early season catch of bunker has been increasingly difficult and less successful each year. Shoreline areas where schools of bunker could be seen from shore especially in the fall have had literally NO bunker. I fear that the impact of the commercial harvest of these critical bait fish is going to negatively affect the fishery for years to come. Perhaps action taken now to drastically reduce the allowable catch will have an impact.

Thank you for the work that you do to preserve the precious resources that we have available in our fisheries and for your attention to this important matter.

Sincerely,

Joseph Lederer

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):

I am writing as a Maryland resident who has lived in St. Mary's County since 2017 and has developed a deep personal connection to the Chesapeake Bay. I am an avid sailor**,** a conservationist, and someone who spends considerable time on and around the Bay. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base.

I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.

The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - **menhaden.**

Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most biologically important deserves particularly careful scrutiny.

The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. **Where and when the fish are removed matters.**

An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.

I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.

For that reason, I urge the Commission to establish **strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months**. Seasonal management would provide a more precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coast wide fishery.

There is also an important management issue that deserves attention. The Commission's coast wide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.

The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.

I respectfully urge the Commission to:
1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.
2. Establish firm seasonal quota periods for menhaden.
3. **Prevent excessive concentration of reduction harvest during the summer months.
4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.
5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.

I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.

We should not wait until the consequences are unmistakable before acting.

The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.

Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.

Sincerely,
Howard W Kympton
St. Mary’s County, Maryland

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission,

I am writing as a Connecticut resident who cares deeply about the health and future of Long Island Sound and our recreational fisheries.

I am increasingly concerned about reports of significant declines in menhaden, or bunker, throughout Long Island Sound, the Connecticut River, and surrounding waters. Menhaden are a critical part of the marine food web and an important forage species for striped bass, bluefish, and other species that make our local fishery so special.

I strongly encourage the Commission to take meaningful action through Draft Addendum II to ensure that menhaden harvest levels adequately protect the forage base along the Atlantic coast, including the availability of bunker as they migrate into New England waters.

This is about more than one species. A healthy supply of forage fish supports the broader ecosystem as well as recreational anglers, charter captains, tackle shops, marinas, tourism, and coastal communities throughout Connecticut and the Northeast.

Please give serious consideration to measures that will provide stronger protection for menhaden and ensure that industrial harvest does not undermine the long-term health of our fisheries.

We need to protect this resource now so that Long Island Sound and the surrounding waters remain healthy and productive for future generations.

Thank you for considering my comments.

Sincerely,

Kevin Sweeney
Stamford, Connecticut

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

The mass harvest of menhaden along the East Coast is pushing a critical marine ecosystem to the brink of collapse, directly threatening the future of Atlantic fisheries. Often called "the most important fish in the sea," menhaden serve as the essential foundational link in the ocean food web. They convert plankton into energy and serve as the primary food source for major commercial and recreational fish species, including **striped bass, bluefish, cod, and tuna**, as well as countless marine mammals and seabirds. By allowing industrial-scale reduction fishing to strip billions of menhaden from coastal waters annually, we are effectively starving the predator populations that rely on them. Without an abundant supply of this single forage fish, the survival rates of juvenile predators plummet, leading to stunted growth, disease, and a systemic decline in biodiversity that will leave tomorrow's oceans dangerously hollowed out.

Failing to curb the overharvesting of menhaden today guarantees a bleak reality for future generations of both fish populations and human communities. Because menhaden are a schooling fish, modern industrial fleets can efficiently wipe out entire localized populations, disrupting the critical spawning cycles required to replenish the species. This localized depletion creates ecological "dead zones" where predatory fish can no longer sustain themselves, permanently altering their migratory patterns and reproductive success. If we do not implement strict, ecosystem-based management limits now, we inherit a collapsed food web where future fish generations cannot recover. This ecological bankruptcy will not only devastate marine life but will also destroy the livelihoods of coastal fishing communities and strip future generations of the robust, biodiverse oceans they have a right to inherit.

Please do what is right and not what is in the best interest of a few large business entities with enormous financial pockets influencing lawmakers.

Thank you
Sal

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic Menhaden Management Board,
I fish Long Island Sound out of southwestern Connecticut, and I'm writing in support of stronger protections for Atlantic menhaden.
As you know Bunker are essential forage for striped bass, bluefish, and other predators. Their availability affects the quality of our fishery and the anglers and coastal businesses that depend on it. I am concerned about increasing reports of a trend developing of fewer bunker in Connecticut and surrounding waters, and I am writing to request the Board to take those local observations seriously.
For Draft Addendum II, I support the strongest proposed reduction in the Chesapeake Bay reduction fishery cap—50%—along with measures that prevent harvest from becoming concentrated during the spring and summer. I also urge the Board to protect the forage base when it sets future coastwide harvest limits and to improve its ability to assess regional menhaden abundance.
Thank you for considering my comments.

Subject: [External] Atlantic Menhaden Draft Addendum II

Importance: High

Categories: Menhaden 2 Auto Replied

To the Atlantic States Marine Fisheries Commission:

I'm writing to urge the Commission to adopt strong forage-fish protections in Draft Addendum II for Atlantic Menhaden.

I fish the Connecticut River, Long Island Sound, and surrounding waters, and over the past three years I've watched the menhaden (bunker) population decline sharply in this region. That decline tracks closely with the large-scale industrial harvest of menhaden farther south, in Virginia and New Jersey, which is removing bunker before they can migrate north and reach our waters in the numbers they once did.

Menhaden are the foundation of our inshore ecosystem. They're the primary forage fueling our striped bass fishery, and their decline is already being felt up and down the food chain — fewer bunker, fewer striped bass, fewer bluefish. The impact isn't just ecological. It's economic: fishermen, guides, charter captains, tackle shops, and marinas throughout the region depend on a healthy forage base and a healthy fishery.

I ask the Commission to reduce the industrial harvest of Atlantic menhaden and to manage this resource with the needs of the broader ecosystem — and the coastal economies that depend on it — front and center.

Thank you for considering my comment.

Subject: [External] Public Comment: Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

September 26, 2026

Dear Mr. Boyle and Members of the Commission,

I am writing to urge the Atlantic States Marine Fisheries Commission to take immediate, strong action to protect the Chesapeake Bay ecosystem by implementing strict catch limits under Atlantic Menhaden Draft Addendum II. Specifically, I support options that substantially lower the reduction fishing allowance in the Bay.

As a resident/supporter of the Chesapeake Bay region, I am deeply alarmed by the unprecedented breeding failures and starvation currently devastating our local osprey populations. Decades of scientific monitoring show a direct link between the lack of mature Atlantic menhaden and the inability of ospreys to successfully raise their chicks.

Menhaden are the ecological backbone of the Chesapeake Bay. Allowing industrial-scale reduction fishing to deplete this critical forage fish at the expense of ospreys, striped bass, and other native wildlife is unsustainable and unacceptable.

Please prioritize the long-term health of the Bay's ecosystem over short-term commercial harvest by implementing the maximum possible protections in Draft Addendum II. Thank you for your time and consideration of these comments.

Sincerely,

Sally C. Prascus

Dear ASMFC,

I am writing to share my concern about the future of the menhaden (bunker) population and the fishery it supports.

Over the past three years, I have observed a dramatic decline in menhaden throughout the Connecticut River, Long Island Sound, and surrounding waters. Industrial menhaden harvest farther south, particularly in Virginia and New Jersey, is an important part of the discussion because removing large numbers of bunker before they migrate north can reduce the forage available to our waters.

Bunker are a critical forage species for striped bass, bluefish, and other marine life, and their abundance has significant implications for recreational fishermen, guides, charter captains, tackle shops, marinas, and coastal communities.

I encourage ASMFC to carefully consider the impacts of industrial menhaden harvest and the need to maintain a healthy forage base for the future.

Thank you for considering the observations and concerns of recreational fishermen and coastal communities as you consider Draft Addendum II for Atlantic Menhaden.

Sincerely,

Michael Lombardozzi

Subject: [External] Save the Menhaden: Draft Addendum II

Categories: Menhaden 2 Auto Replied

To whom it may concern: I have been fishing the lower CT River and eastern LIS on the CT side for just five years, but even in that short period of time I have noticed the marked decline in the menhaden population. During this time span i have seen schools of menhaden disappear, to the point that I haven't seen a single menhaden at all this season. Not a one!!!! This is so concerning because it affects many other fish species and birds as well. Without enough forage, striped bass and bluefish suffer, which has further trickle-down effects, and the local osprey population is literally starving to death.

Please do everything you can to protect this important fish species. Please be as aggressive as you can - and then push it a bit farther. The future of so many animal species depends on your actions to protect menhaden, please do the right thing.

Thank you -
Steve Collins

To whom it may concern,
The absence of Bunker in the Eastern Sound and Ct River this year has been dramatic. They are a critical food source to the health of our fisheries, and I believe that the large scale removal of bunker in the Virginia and New Jersey industrial fleets, before they migrate north is leaving significantly less fish that reach our areas, and have a significant effect on the baitfish population, and contributes to the lack of Striped Bass and Bluefish that we are seeing.

It's time to regulate the Commercial Fleets take of these essential fish.

Thanks,
Bob Fattizzi

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Im am writing today to request that Addendum 2 to reduce or eliminate industrial menhaden fishing in Viginia area waters be approved.

I am a sport fisherman in New England waters and I have recognized a significant decline in the menhaden population everywhere I fish which includes but is not limited to Rhode Island, Block Island Sound, fishers island sound and long island including the pawcatuck and thames river. In my opinion this has reduced the striped bass population in our area significantly. There is a startling reduction of "schoolie" stripers that are less than 28 inches. The last 3 years ive only been catching over slot fish mostly in the high 30" to 45" range. This is very concerning to me. In addition I barely see blue fish any longer. 10 years ago they were almost a nuisance.

Please push to control the industrial fishing for menhaden before its really too late and we loose another species of fish.

Nick Tamburrino

Subject: [External] Menhaden (Bunker) Conservation

Categories: Menhaden 2 Auto Replied

Good Afternoon,

I live in Connecticut and fish recreationally throughout Western Long Island Sound, as well as periodically in Eastern Connecticut with local fishing guides.

Since approximately 2021, I have witnessed what appears to be a dramatic decline in the bunker population in our local waters during both the spring and fall seasons. I have observed a similar trend in Eastern Connecticut. The decline has had a significant impact on the quality of the recreational fishery. Increasingly, the limited concentrations of available bait seem to draw virtually all of the readily catchable fish into one or two areas, resulting in heavy congestion and boat traffic and a substantially diminished fishing experience.

This year, the situation has been particularly concerning. There have been virtually no bunker in many of the areas where they have historically been abundant. Even the Ospreys seem to be struggling to find them.

What is most alarming is the speed and magnitude of the decline. If this trajectory continues, it is difficult not to envision a future in which Western Long Island Sound has dramatically reduced populations of striped bass and bluefish. The historically excellent fall fishing is already a shell of what it was for decades, and the continued loss of the baitfish that supports this ecosystem threatens to further accelerate that decline.

This situation warrants urgent attention and action to better understand what is driving the decline and to protect the health of the Long Island Sound fishery.

Sincerely,

Michael Troy

Subject: [External] Menhaden Conservation

Categories: Menhaden 2 Auto Replied

Good Afternoon,
I live in CT and fish recreationally in Western Long Island Sound.

Since 2021, I have observed a stunning decline in the bunker population in both the spring and the fall in our local waters (and Eastern CT where I fish with guides from time to time). This decline has had a dramatic impact on the quality of our fishery and has resulted in effectively all of the readily catchable fish congregating in one or two areas (where the increasingly scarce bait has been found), making for a significantly less enjoyable experience given the resultant congestion and boat traffic.

This year, there have been virtually no bunker at all. Even the Ospreys seem to be struggling.

The speed of the decline is what is really stunning. At current course and speed, it is not hard to envision a scenario where western Long Island Sound has virtually no striped bass or bluefish within a few years. The “Fall Run” is already a shell of what it had otherwise been for decades.

Urgent action is needed. Thank you.

Sincerely,
Matt Kretzman

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

I believe that menhaden need to be protected in order to return the population to a historic level. Large scale commercial harvesting is depleting the fishery.

I can recall about 20 years ago when my kids were little, it would be common to see huge schools of menhaden in Niantic Bay, Connecticut, with striped bass and bluefish feeding on them. It's been many years since I have seen this.

Please reduce the commercial harvest. I believe that there would be more economic benefit to more people if this was done, as well as the environment would return to a more natural state. Perhaps my kids' kids will see schools of menhaden again.

Thank you.

My son is now 36, he caught and released this striper when he was about 12 fishing under a school of menhaden.

Subject: [External] We must protect our Menhaden/Bunker population

Categories: Menhaden 2 Auto Replied

To Whom it may concern,

Over the past three years, we have watched the menhaden (bunker) population decline dramatically throughout the Connecticut River, Long Island Sound, and our surrounding waters.

This decline is directly tied to the industrial harvest of menhaden occurring farther south, particularly in Virginia and New Jersey. Large-scale removal of bunker before they migrate north is leaving significantly less forage available for our waters.

Bunker are the foundation of our inshore ecosystem and the primary forage driving our striped bass fishery. We are already seeing the consequences—fewer bunker, fewer striped bass, fewer bluefish, and fewer opportunities for the fishermen, guides, charter captains, tackle shops, marinas, and other businesses that depend on this fishery.

We need to protect the bunker and dramatically reduce industrial menhaden harvest.

David Hartikka

Subject: [External] Atlantic Menhaden Draft Addendum 2

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission,

I am a full-time charter captain based out of Old Saybrook, Connecticut, at the mouth of the Connecticut River. I have been running charter fishing operations for 16 years and currently employ four other fishing guides. I am writing because I am seriously concerned about the future of my business and the future of the recreational fishing industry throughout the Northeast.

For more than 25 years, I have watched the Connecticut River and Long Island Sound support an enormous population of Atlantic menhaden. Historically, millions of menhaden have entered the Connecticut River and surrounding waters every year. They are the foundation of our inshore ecosystem and, more importantly to my business, they are what drives our striped bass fishery.

Over the past three years, I have watched the menhaden population decline to the point where there is now **virtually no bunker left in the Connecticut River, Long Island Sound, or the adjacent rivers.**

The consequences are already being felt.

There are significantly fewer striped bass. We have virtually no bluefish. The lack of menhaden has directly correlated with the decline in the abundance of the predatory fish that depend on them. There simply isn't enough forage here to support the fishery we have historically had.

This is no longer a warning about what might happen. We are watching it happen right now.

The fishery is on the verge of collapsing, and I believe immediate action is necessary. We need to dramatically reduce the amount of menhaden being removed by the industrial reduction fishery and put the health of the ecosystem ahead of the interests of the reduction industry.

The economic consequences extend far beyond charter captains. Striped bass are the number-one target species for the majority of inshore recreational fishermen in the Northeast. The striped bass fishery supports charter captains and guides, but also tackle shops, marinas, boat dealers, fuel docks, restaurants, hotels, boat manufacturers, and countless other local businesses.

I employ four other guides. If this continues, **my business and hundreds of other charter operations and fishing guides throughout the Northeast are at risk.** The economic impact of a healthy recreational striped bass fishery reaches thousands of people and businesses.

We need to look at the scale of the economics here. We are allowing a relatively small industrial sector to remove enormous quantities of a forage species that supports an entire coastal ecosystem and a massive recreational fishing economy.

The Atlantic menhaden fishery needs to be managed for the health of the entire ecosystem—not simply for the benefit of the companies harvesting them.

I am urging the Atlantic States Marine Fisheries Commission to take immediate action to dramatically reduce industrial removal of menhaden and increase protection of this critical forage species.

Please listen to the people who are on the water every day. For those of us who make our living on these waters, the decline is impossible to ignore. We have watched the bunker disappear, and we are now watching the fishery that depends on them disappear with it.

We need to protect the bunker. We need to reduce the industrial harvest. And we need to do it now, before the recreational striped bass fishery and the businesses that depend on it are pushed beyond the point of recovery.

I would welcome the opportunity to speak with the Commission or its staff and provide firsthand observations and information from the Connecticut River and Long Island Sound.

Thank you for your consideration.

Sincerely,

Captain Mike Roy

Categories: Menhaden 2 Auto Replied

Thank God, New Jersey has this 3 mile rule on commercial bait fishing, even though Canadian boats are in our waters, pillaging the bunker stocks I fished in Chesapeake Bay, Virginia, and what I saw was the most unbelievable thing vacuum boat, destroying the Chesapeake Bay by taking all the bait I thank them, though cause cobia fishing is great in New Jersey now I know they have to do commercial bunker fishing, cause they use them as so many products so I don't know what I'm sending is even gonna help but yes, I agree. There's way too many bunker being taken out the whole ecosystem of the Atlantic ocean relies on that fish. These greedy processes are unsustainable. My name is Nicholas Hess? My phone number is 201-780-7046 and hopefully this will help you Sent from my iPhone

Subject: [External] Stop the over fishing of Menhaden

Categories: Menhaden 2 Auto Replied

I am reaching out to comment on the over fishing of Menhaden. The single most important food chain in our oceans. Me must stop allowing these commercial fisheries to net and deplete our oceans of such an important food chain for so many fish species, mammals and birds.
Get the boat out and send them home! THIS MUST END or the consequences will be far more severe once there are no more menhaden.
Thank you.

Subject: [External] Menhaden Board Meeting

Categories: Menhaden 2 Auto Replied

I have been surf spin and fly fishing for over 30 years. I have been concerned about diminishing Menhaden along the Rhode Island and Massachusetts shores since at least the Bush era. Even then, there was concern about the harvest of menhaden for reduction by companies such as Omega. Given the poor state of the striper fishery along the shore areas, as reflected by the poor recruitment and low number of schoolies, it is time for significant changes to the menhaden management.
I would Urge you to ban harvesting manhaden for reduction purposes. I would continue to allow manhaden harvest for bait purposes at an amount that conserves the species.
Thank you,
Richard Rubin

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission Commissioners,

I am writing to submit my formal public comments regarding Draft Addendum II to Amendment 3 of the Atlantic Menhaden Fishery Management Plan. While I currently reside in Illinois, I grew up in New Jersey and retain a deep, lifelong connection to the health of the Atlantic coast. As an avid birdwatcher who regularly observes Ospreys in Long Beach Island, NJ - including this past August after I learned of the severe Osprey chick survival challenges - I am deeply concerned by the ecological collapse of Osprey nesting success in the Chesapeake Bay driven by localized menhaden depletion.

Public resources belong to the wider public, and ecosystems do not respect state borders. Industrial depletion in our shared marine nurseries threatens avian and aquatic wildlife across the entire Atlantic Flyway. To implement true, precautionary ecosystem-based management that gives these foundational species a fighting chance, I urge the Board to adopt the following specific options:

* Section 3.1: Support Option C1e (with C2a limits) to link the Chesapeake Bay Reduction Cap directly to the coastwide Total Allowable Catch (TAC). This will cut the current cap by 50% immediately and ensure the Bay's ecosystem is protected proportionally if future coastwide cuts are made.

* Section 3.2.1: Support Option B2 (25% / 25% / 50% Quota Periods) to prevent the industrial fleet from heavily concentrating harvest early in the season when breeding Ospreys experience their highest forage demands.

* Section 3.2.2: Support Option B (Overage Payback) to ensure that seasonal quota limits function as enforceable conservation regulations rather than voluntary targets.

* Section 3.3: Support Option B (Three-Year Revisit) to mandate that the Commission regularly re-examines and adapts the cap every three years as new, localized predator-prey data becomes available.

Thank you for taking precautionary action to protect the foundation of our marine and avian food webs.

Sincerely,

Kirk Davidson

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Mr. Boyle and Members of the ASMFC,

I am writing to submit my public comments regarding Atlantic Menhaden Draft Addendum II. As an advocate for the health of the Chesapeake Bay and the broader Atlantic coastwide ecosystem, I strongly urge the Commission to implement management options that prioritize localized biomass protection and strict accountability.

My specific positions on the options are as follows:

- **Issue 1: Seasonal Quota Allocation – Support Option B3 (Four Periods, 25% each) WITH Strict Paybacks.** Evenly dividing the harvest across four separate periods throughout the year is the most balanced way to prevent intense, localized depletion during critical wildlife breeding and foraging seasons. This option must be paired with **Option B (Quota Period Overage Payback)** to ensure immediate accountability.
- **Demand for a "No-Rollover" Rule:** While I support Option B's overage payback, I strongly **oppose the automated rollover of unused quota** between periods. Allowing unused quota to accumulate into later periods creates a massive loophole that lets industrial fleets heavily concentrate their fishing pressure all at once. I request that the final rule explicitly prohibit inside-the-season rollovers.
- **Issue 2: Chesapeake Bay Harvest Cap – Support Option C1e (50% Reduction) and Oppose Option C2a.** The Chesapeake Bay is facing a severe ecological crisis, evidenced by starving osprey populations and poor striped bass recruitment. The industrial reduction fishery harvest cap must be cut by 50% to **25,500 metric tons**.
- **The Proportional Link Trap:** I strongly **oppose Option C2a (Linked Cap)**. While the cap should shrink if coastwide stocks decline, a proportional two-way link means the Bay cap would automatically increase if the coastwide TAC goes up. Tying the fate of a fragile, localized estuary to broad, coastwide ocean models is a dangerous math flaw that allows coastwide increases to override severe, localized depletion in the Bay. The ASMFC must establish a **hard, fixed ceiling of 25,500 metric tons** that cannot be triggered upward by coastwide changes.

Thank you for your time and for taking necessary, precautionary steps to protect the most important fish in the sea.

Sincerely,
Chris Wright

Subject: [External] Menhaden

Categories: Menhaden 2 Auto Replied

Dear Members,

I just read an article that said there were a lot of comments from the local community against reducing the menhaden catch limit. I completely understand that in these times, that people are desperately trying to hold onto their source of income and traditional ways of life. That said, the logical response would be to REDUCE the catch limit so that they actually have a sustainable livelihood well into the future. The stalling tactic of "waiting for the science" is just that, and I imagine there would still be significant resistance if the science does show that the fishery is depleted (as I imagine it will). History is replete with examples of fisheries that have collapsed because of this "get it all now" mentality. And if that were to happen here, those objecting would definitely be in a hard place. Finally, just because they are local and able to turn out in force to protest, this is not solely their resource. The health of this fishery is everybody's concern, even if they were unable to attend a meeting. I know it is hard not to be sympathetic and to let emotions (and monied interests) influence the decision making process, but please do the right thing and SIGNIFICANTLY reduce the allowable catch.

Thanks for all that you do!

Mike Horan

Subject: [External] Menhaden industrial fishing: please halt it

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

I am writing to say I support shutting down the menhaden industrial fishing industry. The harvest is contributing to the starvation of multiple species that rely on menhaden. The resurgent osprey population in the Bay is a wonderful success story, and the menhaden fishery is leading to their depletion again. Watermen need the healthy fisheries that the menhaden support.

The menhaden are necessary for species of ASMFC concern, including rockfish, bluefish, weakfish and spiny dogfish. They are also necessary for multiple bird species.

Please stop the harvest.

Thank you.

Susan M. Sterett

I am a lifetime resident of the New Jersey shore, and I currently own a large tract on the Bass River. New Gretna is quite attached to our nesting Osprey, Greta and River. To say they are struggling is an understatement. Only one of their chicks survived the summer, but is likely too weak to survive migration. As a fisherman, I have watched Omega and Cooke decimate our population of bunker with their fleet of factory reduction vessels and spotter planes. This is not traditional fishing. It is a greedy Canadian company exploiting our waters and causing catastrophic harm. Why? For the greedy politicians who received money for things like inauguration parties. It needs to stop. Didn't we learn a lesson from the market hunting of the past? Please exhibit some common sense.

Subject: [External] Help Osprey's nesting at the Chesapeake Bay

Categories: Menhaden 2 Auto Replied

Dear Friend,

Thank you very much for giving me the opportunity to comment on the Chesapeake Bay menhaden fishing limits.

I support cooperation between companies and the public on fishing in the Chesapeake Bay.

I started counting migrating birds when I got cancer in 2017. I joined a group near my house, and it was a godsend. I couldn't travel and I had to be close to home in case I got sick.

Learning about migrating Ospreys and viewing their silhouettes against the blue sky and white clouds is one of the great joys of my life. I fell in love with them. They have a long wingpan when viewed from below and their wings almost seem to have a "shoulder". Later I read they have special talons and body so they can literally "dive" into the water and grab a fish to feed their young.

When I heard at a talk at my bird club that Ospreys aren't nesting around the Chesapeake because there are no menhaden fish to feed their young I was very upset. I had just retired in 2020 and I planned to enjoy watching these gorgeous birds as my hobby. Instead, I am spending my retirement years reading about environmental losses, loss of wetlands and lakes and loss of ocean and bay water quality.

Please help us control the one thing that we can help birds with and that is sharing natural resources.

I know corporations are helpful citizens in many cases, but their need to make money shouldn't come at the absolute expense of my passion.

I support

- Option B4: 50% reduction of the Bay Cap resulting in 25,500 MT cap
- Option CIE: 13.6%
- Option C2A: Upper limit: 51,000 mt
- Option B2: Even Length & uneven harvest
- Revisit Provision every 3 yrs

Thank you very much for your help.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission:

As a long-time volunteer at Owl Moon Raptor Center in Boyds, Md., I've witnessed the devastating impact that the dwindling menhaden fishery is having on ospreys across the Chesapeake Bay region. Far too many of the ospreys that reach Owl Moon are emaciated or starving, and we're forced to euthanize many who are unable to survive -- much less return to the wild.

As such, I'm writing to urge ASMFC to adopt the common-sense, conservation-minded recommendations proposed by the Virginia Saltwater Sportfishing Association to help achieve the maximum 50% reduction in menhaden harvested from the Chesapeake Bay. Specifically, I hope you will help implement the options outlined below:

3.1 Chesapeake Bay Reduction Fishery Cap Amount

Option C1e: To reduce the Chesapeake Bay CAP by at least 50 percent in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).

Option C2a: To set the maximum upper limit in any future change at the current level of 51,000mt.

3.2 Chesapeake Bay Cap Distribution

Option B2: To establish three even length quota periods for the Chesapeake Bay Cap, distributing the harvest at 25% in period 1, 25% in period 2, and 50% in period 3.

Option B: Provides any underage of Quota Periods 1 or 2 be rolled into Period 3 of the same fishing year. Any underage in Quota Period 3 would not be reallocated. Any overages would be deducted from the same quota period in the following year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision

Option B: Revisit the Chesapeake Bay Cap every 3 years.

Today, we are witnessing all the signs of a devastating osprey population collapse. As a recent article in the Bay Journal reported, “Osprey breeding continues to falter around the Chesapeake Bay, a new survey has found, with the meager hatching and survival of chicks this year well below what is needed to maintain the population.”

We must do more to save these stunning wild creatures, and I urge you to take strong action to achieve the maximum 50% reduction in menhaden harvested from the Chesapeake Bay.

Thank you,

Catherine Lemp

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Hello,

My name is Scott and I am a lifelong Virginian native to Virginia Beach, an avid outdoorsman, and lover of the Chesapeake Bay. I've fished the Bay extensively for a couple of decades and have spent countless hours on the water. Because I love the Bay, I am writing to advocate for the passage of the Atlantic Menhaden Draft Addendum II reducing the menhaden cap and dividing the harvest into seasonal periods. What Omega, Cooke, and Ocean Harvesters (I'll collectively refer to them as Omega as they are all the same) are doing calls for common sense regulation as more data is being collected. It is telling that Omega has lobbied extensively against that independent data collection in the first place. This addendum would serve to support local commercial watermen, recreational fishermen, bird watchers, whale watchers, and the American people who rely on the Bay for connection with nature, God, and each other. This over-consumption is unsustainable. While I recognize Omega has been fishing the Bay for decades, it is notable that it is taking them longer to fill their cap while they have greater access to advanced technology creating a more efficient harvest. The notion that a species cannot be over-harvested to decline or failure, which Omega continually asserts is the case for menhaden, is kindly untrue, but frankly ridiculous. Just ask Virginia elk, the passenger pigeon, or American bison. If you're reading this and have never seen one of the net sets in person, I'd be happy to take you out on my boat any time to watch it. While the bycatch of drum, rockfish, cobia, croakers, spot, etc. is heartbreaking, it is important to remember that the most important fish being killed in the nets are the menhaden. My wife and I are returning to the Tidewater area in the coming year and a massive piece of that decision is to show our son the Bay that we know and love. Omega's consumption has already changed the Bay enough (ask anyone who actually spends time on the water). A large number of us, with actual fisheries and environmental experts in this group, have legitimate fears that if left unchecked Omega will kill the Bay. This addendum would be a phenomenal step in the positive direction. The public outcry is strong for a reason and I ask that you listen to Americans up and down the coast! I urge you, as officials tasked to foster the Atlantic, please protect our resource now and pass this addendum in full.

Thank you from all of us!

Scott

Subject: [External] Ospreys/Mehaden public comment

Categories: Menhaden 2 Auto Replied

I'm a bird of prey rescuer in Maryland. Seeing starving/dying juveniles ospreys has been among the most heartbreaking tragedies I've witnessed as I rescuer. This has been playing out for a few years with fewer and fewer ospreys being seen along the Chesapeake. This past summer, there were no active nests that I was aware of near my house. Normally there are several. This is a total loss of active, successful osprey nests within 2 miles of my house. This is not sustainable for the species (at least along the Chesapeake).

We must do better as humans. We have the possibility of turning this around and we need to make certain ospreys have enough to eat. That won't be done until we put further limits on the commercial/industrial menhaden fishing industry – those with spotter planes and ships that are depleting the Atlantic and the Chesapeake of menhaden. We don't have time to think about this, we don't have time to wait for another study, we don't have time to wait for another meeting.

We are watching, in real time, what very well could be the extinction (state and/or national) of a much-loved, charismatic species – the osprey. And we have the potential to stop this by further limiting the menhaden catch. Please do so and do it quickly.

Subject: [External] Public Comment - Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Hello,

I am writing to let you know that I support reducing the fishery cap of menhaden in the Atlantic by 50% and creating quota periods to distribute harvest under the cap more evenly throughout the fishing season.

I have been closely following the migrating Chesapeake osprey population since I moved to Kent Island in 2022. They are a source of deep fascination for me and I watch them closely each season. I have seen the decline in the amount of young produced with my own eyes. And, I have read the scientific reports coming out of William & Mary's Center for Conservation Biology. Last year, I downloaded Osprey Watch, the citizen's science app/tool to help track the osprey nests and numbers of young produced. In just one season, there was a major decline.

I am deeply saddened and concerned about the Osprey population! Just out of college, I worked in Washington, DC on The Hill in environmental conservation, specifically overfishing. I worked for The Marine Fish Conservation Network, American Oceans Campaign and The Ocean Conservancy, and feel I have a particular understanding of the issues facing the Atlantic fisheries. I have no doubt that the overfishing of menhaden is contributing drastically to the osprey crisis, if not fueling it entirely.

I am begging you to please put a cap on the fishery of menhaden in the Atlantic by 50%. Please, also create quota periods to distribute the harvest under the cap more evenly throughout the fishing season.

We cannot risk losing this incredible species when we know what is wrong and it is in our power to correct it.

Thank you so much for your time.

Sincerely,
Cristina Montejo

Comment

Public Comment to: ASMFC Menhaden Board Members

From: Dale William Neal, Richmond, VA

I would like to share four points and a simple formula for a path forward on the upcoming TAC vote and Reallocation.

1. “Wildlife eat Menhaden, people don’t.”
Industrial reduction fishing is not about catching seafood, it’s an outlier to what ASMFC shepherds. Menhaden should be prioritized as a bait fish. It is a truly sustainable and economically sound choice. As was stated by a board member in your last meeting, “they are much more valuable when turned into Lobster rather than dog food”.

2. “Menhaden pack the most powerful nutrient punch available for wildlife.”
They are called a “keystone species” for that reason. In the Atlantic, Menhaden provide >50% more essential nutrition per gram than Atlantic Herring. In the Chesapeake Bay that number is >50% more than Mullet and River Herring, and 200-300% more per gram than Bay Anchovy or Silverside. Menhaden mature to upwards of 3/4 pound (300 grams) or larger. Bay Anchovies never reach over 7 grams, vastly smaller than even juvenile menhaden. No other biomass of fish can replace Menhaden in the critical role of supplying wildlife needs for growth, reproduction, or migration.

3. “There are many factors causing issues.”
I agree with Reduction Industry spokespeople—warmer waters, migration changes, invasive species, coastal development, runoff, pollution, and fishing pressure—are all factors in the critical ecosystem changes we are witnessing. That on its’ own should give you more impetus to conserve what’s left. And let me state the obvious, fishing pressure is the only factor you control. Everyone else is depending on you to get your piece right.

4. “Jobs: The Coastwide Bait Industry vs. The Reedville Reduction Industry.”
According to NOAA Fisheries there are an estimated 1-2,000 independent bait and tackle shops still left in business along the Atlantic Coast. Include non-exclusive retailers—such as marinas, gas stations, coastal hardware stores, convenience shops, and fishing piers—the total number of physical locations selling bait along the coast reaches well over 4,000. That’s a lot of indirect jobs depending at least partially on a sustainable menhaden supply. Now add on the 10,000-15,000 lobstermen, crabbers, and commercial hook-and-line fishermen who depend on a consistent and affordable supply provided by the many watermen who catch those menhaden. Those are all real jobs and businesses.

The reduction industry in Reedville routinely employs far less than 400 workers. Fewer than 100 work year round.
More than 10% are foreign guests on H-2B visas, 15-20% live outside of Northumberland County. The county of 12,000 residents currently reports over 4,000 total jobs and an annual GDP of nearly $500 million. The reduction industry reports $29m in annual Virginia payroll and benefits. Reedville is located within 100 miles of the DC metro area (population 6 million) and is growing as a prime coastal destination for retirement and tourism. The median age in the town is 65.5. Half of the residents are retired. Real estate values are above state averages. One third of the homes are second or vacation homes.

Industry profits from reduction fishing go to a multi-billion dollar global corporate conglomerate based in Canada.

An Equitable and Sustainable Solution
(1) Reduce TAC 30%
(2) Reduce the Virginia share to 60%
(3) Increase the other states share to 40% (increasing their metric tonnage >12%)

Dear Commissioners,

The alarming declines in Osprey populations around the Chesapeake Bay bring back disturbing memories of the birds' earlier population collapse during the era of DDT overuse. That chemical thinned the birds' eggshells, resulting in a reproductive shortfall each year as the population dwindled until the 1972 DDT cancellation allowed the birds to slowly recover. Everyone who cares about the Bay in 2026 should be grateful for the work of those who identified the problem and gave the Ospreys an opportunity to rebound.

We are facing a regional collapse today that started in the southern Chesapeake Bay and has moved north through much of the area. Today's breeding shortfalls are worse than those during those grim years when DDT disrupted their endocrine systems. Research this time has revealed that the chicks do hatch, but they are starving due to parents' inability to catch life-sustaining fish. Specifically, the key Bay protein source of menhaden is not available in sufficient quantities to support the lived of the iconic seahawks of the Chesapeake Bay.

Ospreys are more than beautiful symbols of Chesapeake region. They are living reminders of the struggle to keep our environment healthy and our fisheries robust and resilient. Please reduce the menhaden harvest by 50% or more to give Ospreys a second chance. People today and tomorrow will thank you for fulfilling your important stewardship responsibilities.

Yours truly,

Julie Dunlap

Hello,
Please reduce the overfishing of Atlantic menhaden in the Chesapeake Bay and surrounding waters.
I am a resident of Mayo, Maryland -- a part of Edgewater. My family and I moved to this area two years ago after a long search. The bountiful, thriving local wildlife in this area was a driving piece of our decision to purchase a home and raise our young son in this community. Unfortunately, we have watched nearby osprey nests fail and read accounts of local birders and naturalists who are actively monitoring as the health of these birds declines.
Please stop the aggressive reduction fishing of the fish that sustain this food web.
Thank you

Subject: [External] OSPREY DECLINE

Categories: Menhaden 2 Auto Replied

The osprey of Ct and the East coast are in danger of severe decline that they may not be able to recover from if action is not taken NOW. Time is of the essence. The osprey of Ct are fol 80% last year. THEY ARE STARVING. After the heroic effort of recovering from poisoning by DDT, they now are facing a manmade problem o ofverfishing. There may be other enviromental reasons for the decline of menhaden, which is urgently being studied. But overfishing for this bait fish when numbers are so low will cause unreversible damage. I have been an Osprey steward for over ten years. ALL my nests, which had been so steady and productive in the past- they all failed this year. The female osprey were crying out for food to be delivered by the male as they incubated. Then they finally had to leave the nest to get food for themselves. Osprey usually mate for life but it is unclear if they stayed together went off alone as they were desparate. This year it was so confusing as a steward. The females came and went, leaving the eggs unattended for hours. They deserted their nests and never came back. I hope they found a better food source inland. None of my nests produced even one chick. My favorite place to kayak on Great Island Old Lyme was deserted. Only 5 chicks seen where usually there were 30 nests with 1-3 chicks per nest. I ask thet fishing of menahden be reduced by 50% immediatley. dleaying one more season will be a fatal mistake.

Dear Sirs, We are writing in support of the complete closure of the rendition harvest or for a 50% harvest cut for 2027. We have lived on the Chesapeake Bay since 1982 and have followed the annual rise and fall of the Osprey population along with on-going bay restoration efforts. It is destressing to witness the last few years with fewer fish to support the Osprey population during the breeding season due to commercial harvesting of menhaden. Subject: [External] Subject: Public Comment — Chesapeake Bay Menhaden Reduction Fishery

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic States Marine Fisheries Commission:

I am writing as a Virginia resident who lives on the water in Heathsville and has a direct and personal interest in the health of the Chesapeake Bay and the wildlife that depends upon it.

I respectfully ask the Atlantic States Marine Fisheries Commission to adopt substantially stronger protections for Atlantic menhaden in the Chesapeake Bay as it considers Draft Addendum II.

Specifically, I ask the Commission to substantially reduce the current **51,000-metric-ton Chesapeake Bay Reduction Fishery Cap**, establish meaningful seasonal limits on the industrial reduction fishery, and consider linking the Bay cap more directly to changes in the coastwide total allowable catch.

I understand that the current coastwide stock assessment does not classify Atlantic menhaden as overfished and does not find that overfishing is occurring. My concern is not that the entire Atlantic menhaden population has necessarily collapsed.

My concern is what happens when very large quantities of an important forage fish are removed from a particular ecosystem — the Chesapeake Bay — during particular times of the year.

My personal observations

I live on the water in Heathsville, Virginia, and have spent considerable time observing the wildlife around my home and throughout the surrounding area.

One change I have personally noticed is a **noticeable reduction in the number of ospreys and eagles that I see in my neighborhood**.

I recognize that my observations alone cannot establish the cause of that change. I am not claiming that the menhaden reduction fishery is solely responsible.

However, the decline I have personally observed concerns me because menhaden are an important forage fish for numerous Chesapeake Bay predators.

That makes the availability of menhaden in the Bay an issue that deserves serious consideration when establishing the amount of industrial harvest that should be permitted.

The ASMFC itself has identified possible downstream effects on menhaden predators as one of the concerns underlying the current Draft Addendum. The Commission has also noted concerns about declining pound-net harvest and catch-per-unit-effort in the Bay and the increasing concentration of reduction harvest during the summer months. (ASMFC)

The Chesapeake Bay deserves specific protection

I believe the management question should be more than simply whether the Atlantic menhaden population is sustainable on a coastwide basis.

The Chesapeake Bay is a unique estuarine ecosystem and an important nursery area for many species. The current 51,000-metric-ton Bay cap was itself established as a precautionary measure in response to concerns about localized depletion, and the cap was subsequently reduced to its current level in recognition of the Bay's ecological importance. (ASMFC)

The Commission is now considering reducing that cap by as much as **50 percent** and considering seasonal quota periods to distribute the harvest more evenly throughout the fishing season. (ASMFC)

I believe those options deserve serious consideration.

Timing and concentration of harvest

I am particularly concerned about the concentration of industrial reduction fishing during the spring and summer.

Even if the total Atlantic menhaden population remains sustainable, removing very large numbers of menhaden from the Chesapeake Bay at a time when predators and other fisheries may depend heavily upon them could have localized consequences.

The Commission's current proposal recognizes this concern by considering three quota periods specifically intended to prevent excessive concentration of reduction harvest during the spring and summer. (ASMFC)

I urge the Commission to make those seasonal protections meaningful and enforceable.

The impact on local quality of life

There is another issue I believe deserves recognition.

The odor coming from the menhaden processing operation in Reedville can be extremely unpleasant. As someone who lives in the area, I have personally experienced the odor, and there are times when I find traveling to nearby Reedville unpleasant enough that I simply avoid going there while the plant is processing a trip.

I recognize that an unpleasant odor by itself is not a reason to establish a menhaden harvest quota.

I mention it because the people who live, work, boat and recreate in this area experience the effects of this industrial operation in ways that may not be reflected in an economic analysis of the fishery.

The economic value of the Chesapeake Bay should include not only the value of the menhaden reduction industry, but also the recreational, environmental, tourism and quality-of-life values associated with a healthy Bay and its surrounding communities.

My requested management actions

I respectfully ask the Commission to:

1. Substantially reduce the Chesapeake Bay Reduction Fishery Cap from its current 51,000 metric tons.

I encourage the Commission to give serious consideration to the **50% reduction option**currently under consideration.

2. Establish meaningful seasonal quota periods.

The goal should be to prevent a disproportionate amount of the annual harvest from being removed during the spring and summer.

3. Consider linking the Bay cap to the coastwide total allowable catch.

If the coastwide TAC is reduced, the Bay harvest allowance should not remain effectively insulated from that reduction.

4. Increase Bay-specific monitoring.

I encourage the Commission to improve monitoring of menhaden abundance, harvest locations, harvest timing, predator populations and the relationship between menhaden availability and other Bay fisheries.

5. Periodically reevaluate the Bay cap.

The cap should be adjusted as new scientific information becomes available rather than treated as a permanent entitlement to remove a predetermined quantity of menhaden from the Bay.

6. Apply a precautionary, ecosystem-based approach.

Where there is uncertainty concerning the ecological consequences of removing large quantities of an important forage fish from the Chesapeake Bay, I believe the appropriate response is to err on the side of leaving more menhaden in the ecosystem.

I recognize that the menhaden reduction industry provides jobs and economic activity in the Reedville area and has a long history in the region. I am not asking the Commission to disregard those economic interests.

I am asking that those interests be balanced against the ecological and economic value of the Chesapeake Bay itself.

As someone who lives on the water in Heathsville, I have a personal stake in seeing the Bay remain healthy and productive for the wildlife, fisheries, recreational users and communities that depend upon it.

I respectfully ask the Commission to take this opportunity to substantially reduce the Chesapeake Bay menhaden harvest, establish meaningful seasonal protections, and continue developing a management system that protects adequate menhaden availability within the Bay.

Thank you for considering my comments.

Respectfully,

Richard P. Krueger, Jr.

To whom it may concern:

As a person of faith and I am a sincere person of faith, a retired ordained Deacon in the Episcopal Church in Connecticut and a member of the Third Order of Saint Francis (Episcopal). I believe that we all are called to be care for creation. It is my understanding that the The Atlantic States Marine Fisheries Commission is considering changes to the amount of menhaden that can be harvested from the Chesapeake Bay. As a person of faith, I am urging the commission to reduce the fishery cap by 50 percent, a precautionary measure to ensure that menhaden, a key foundation fish and a prime food source for Ospreys, are not put in even greater jeopardy.Last year Connecticut Audubon's Osprey Nation recorded its lowest breeding success since the statewide community science program launched in 2014 to monitor the birds. This year is looking even worse. Osprey and other species that rely on menhaden do not have years longer to wait. Decisive action is needed now. I ask you to support this change in order to protect creation.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear James Boyle and Members of the Atlantic Menhaden Management Board,

I am writing to express my strong support for maximizing conservation measures under Draft Addendum II. Specifically, I urge the Board to adopt options that significantly reduce the Chesapeake Bay reduction fishing cap by 50% and implement stricter localized management.

As a passionate recreational angler, I travel to **Martha's Vineyard Island** annually, investing tens of thousands of dollars into the local economy through charters, lodging, bait shops, and restaurants. Over the last few seasons, the decline in our local fishery has been devastating. This year, my trips have yielded dismal striped bass fishing and an alarming, complete absence of menhaden schools in our waters.

Industrial reduction fishing in the Chesapeake Bay—the primary nursery for the Atlantic striped bass stock—is choking out the forage base that northern migratory fisheries rely upon. When menhaden are over-concentrated or depleted at the source, the ecological ripple effects are felt directly by anglers like me on the water in New England.

Striped bass cannot recover without an abundant supply of menhaden. I urge the Board to prioritize the health of the broader ecosystem and the multi-billion-dollar recreational fishing economy over industrial harvest interests, whose economic impact is dwarfed by the recreational angler community. Please enact the maximum conservation protections available in this addendum.

Thank you for your time and leadership on this critical resource.

Sincerely,

Emmit Hoyl

Categories: Menhaden 2 Auto Replied

To whom it may concern:

I support fisheries management in the Chesapeake Bay that is firmly based on the best available science and considers the health of the entire ecosystem.

Atlantic menhaden are a critical forage species for striped bass, birds, and other wildlife - especially the Osprey. I urge the Commission to prohibit industrial-scale commercial menhaden fishing within the Chesapeake Bay, consistent with the restrictions adopted by the other Chesapeake Bay states. Virginia should not remain the exception.

Commercial harvest can continue in appropriate ocean waters, but the Bay itself should be protected as an essential nursery and feeding area. Please prioritize the Bay's long-term ecological health over short-term commercial interests.

Sincerely,

Rob Canora

Categories: Menhaden 2 Auto Replied

To whom it may concern- I live in Fair Haven, NJ in a home on the Navesink River. 10 years ago I installed a stand for an osprey nest next to my dock and have been watching the nest be used every year since. I was alarmed to see nest failure in the last two years. By that I mean that the adults returned and sat on the nest but no chicks were ever visible. This is very alarming as the ospreys were a very active part of the local ecosystem. I am not sure of the cause but I would report seeing less fish being caught and returned to the nest. The ospreys are very vocal. I have observed that the male will fly around announcing his catch and then perch in my tall trees to prepare that catch, by tearing out gills and other non edible parts, before returning to the nest to feed the roosting female. This activity has been less common over the past 2 years and I would say that it is likely due to less menhaden available for catching. The caught fish also appear to be smaller. It is heartbreaking that we are allowing our ospreys to be starved, please pass the addendum to reduce the permitted amount of menhaden that can be harvested so that our ospreys can thrive!

Sincerely,
Bonnie Torcivia

Subject: [External] Menhaden Fishing vs Wildlife

Categories: Menhaden 2 Auto Replied

Please stop believing that we can greedily strip our ecosystems and expect it to continue to provide those resources. Companies will steal life from the wildlife of the bay for their own profit until they see the end of the existence if the resource. Then they call it a successful profit margin for past years and then pivot to a new venture leaving devestation in it's wake. They dont care about Virginia or Maryland or the bay or who and what they impact. This is why they must be regulated to do so.

We regulate the fishing industry or look like a fool as the ecosystem stops serving the humans that abused it. Make the change- every good decision sets the example and sends ripples into forever.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Members of the Atlantic Menhaden Management Board,

I am writing to support substantial additional protections for Atlantic menhaden and to request that Draft Addendum II include stronger measures addressing concentrated commercial harvest, particularly in nearshore and estuarine waters.

Menhaden are not simply another commercial species. They are a foundational forage fish supporting striped bass, bluefish, weakfish, marine mammals, seabirds, and the broader Atlantic coastal food web.

ASMFC's ecosystem reference points recognize this ecological role. The 2025 assessment also identified fishing mortality above the ecological target and indicated that a TAC reduction of 50% or greater would substantially reduce the probability of exceeding that target.

Just as importantly, ASMFC acknowledges that its current assessment cannot determine menhaden stock status at smaller spatial scales. A healthy coastwide biomass does not establish that intensive harvest cannot reduce forage availability within an individual bay, inlet, migration corridor, or nearshore region.

I therefore request that the Board add or consider the following measures in this Addendum:

1. **A meaningful coastwide reduction in commercial harvest**, including consideration of a 50% or greater TAC reduction consistent with the ecological reference-point analysis.
2. **Daily, weekly, and seasonal vessel limits** in addition to the coastwide TAC. Annual quotas alone do not prevent enormous quantities of forage from being removed from one location over a very short period.
3. **Seasonal nearshore closures during major predator and bird migrations**, including consideration of April 1–June 15 and September 1–November 30. Final regional dates can be established using the best available migration data.
4. **A coastwide nearshore and estuarine harvest buffer**, with seven miles from shore as a starting point for consideration. Bays, inlets, and other concentrated forage areas should receive comparable protection.
5. **Limits on industrial harvesting capacity and technology**, including consideration of restrictions on spotter aircraft, vessel capacity, and other technologies that enable extremely rapid removal of concentrated schools.
6. **Stronger bycatch monitoring and accountability**, including electronic or independent monitoring where appropriate and substantial penalties for excessive or preventable bycatch.
7. **Independent verification of landings and fishing activity**, including vessel tracking, electronic reporting, and dockside verification for high-volume harvesters.

8. **Meaningful consequences for quota violations.** Illegal or excess harvest should be confiscated. Serious or repeated violations should result in escalating fines, permit suspension, and ultimately permit revocation. Penalties should eliminate the economic incentive to exceed regulations.
9. **A per-pound commercial menhaden assessment dedicated to management.** Revenue should directly support state fisheries enforcement, independent monitoring, ecosystem research, and development of improved spatial assessments. The cost of adequately monitoring an industrial fishery should not fall entirely on taxpayers.
10. **Evaluation of the end uses driving reduction-fishery demand.** Fish meal, fish oil, dietary supplements, fertilizer, and aquaculture inputs should be examined individually, particularly where practical substitutes exist. Harvest allocation should account for menhaden's value as forage, not simply market demand for the landed product.
11. **Automatic ecosystem safeguards.** The Addendum should establish measurable triggers tied to forage abundance, recruitment, predator condition, or other scientifically appropriate indicators. Crossing those thresholds should automatically produce additional harvest reductions, spatial closures, or temporary moratoria.

I also urge the Board to address **localized depletion directly**. The inability of a coastwide assessment to measure localized depletion should not become a reason to postpone protection until better models exist. Where uncertainty exists and the potential consequence is loss of forage from important nearshore feeding areas, management should be precautionary.

Atlantic herring provides a warning of how difficult recovery can become after a forage stock is severely depleted. Fisheries management should not require menhaden to approach that condition before stronger protections become justified.

If commercial menhaden harvest is going to continue at substantial scale, the industry should accept equally substantial safeguards: lower harvest, spatial protection, limits on concentrated removals, comprehensive monitoring, strong enforcement, and financial responsibility for the management necessary to sustain the resource.

Menhaden's value cannot be measured solely by the price received at the dock. Their greatest value is the life they support while remaining in the Atlantic ecosystem.

Please strengthen Draft Addendum II accordingly.

Respectfully,

Brandon Sakelaridos

Categories: Menhaden 2 Auto Replied

I strongly agree that menhaden fishing should be drastically reduced, if not eliminated entirely. In 10 years, we have seen an abundance of osprey chicks along nests on the visible horizon, to less than 3-4 since 2022, dying chicks in 2023,24,25 and none this year at all.

Subject: [External] Atlantic Menhaden Draft Addendum II and 2027–2029 Catch Limits

Categories: Menhaden 2 Auto Replied

I strongly believe that meaningful limits should be placed on the harvest of menhaden to ensure the long-term health of our coastal waters, fisheries, and wildlife. Menhaden **are not** just another fish species. They are a vital link in the marine food chain and support countless species that depend on them for survival.

Too often, fishery management focuses on the economic value of a species as a commercial product while overlooking its ecological value. When large numbers of menhaden are removed from the ecosystem, the effects ripple throughout the entire **food web**.

Setting reasonable catch limits is not about eliminating fishing. It is about balancing economic interests with responsible stewardship. When you don't have safeguards in place, intensive harvesting can reduce local populations. This ultimately harms both the ecosystem and the coastal communities that depend on healthy fisheries.

Menhaden also provide environmental benefits beyond their role as prey. As filter feeders, they help improve water quality by consuming plankton and organic matter. In estuaries and bays that already face pollution and environmental stress, maintaining robust menhaden populations can contribute to healthier aquatic ecosystems.

Once a population declines significantly, recovery can take many years. Preventative conservation measures are far more effective and less costly than emergency restrictions imposed after damage has already occurred.

I fully support science-based catch limits that account for both the abundance of menhaden and the needs of the broader ecosystem. Fisheries managers should prioritize sustainable harvest levels, protect important spawning and nursery areas, and regularly adjust quotas based on current scientific data. These measures will help ensure that future generations inherit healthy oceans and productive fisheries.

I strongly support establishing and enforcing limits on menhaden harvest to ensure their long-term sustainability and the health of our coastal waters.

"More bunker in the water means more food for the coast we love. Help us make that the priority this November."

I would suggest a significant reduction or stopping menhaden reduction fishing in Chesapeake Bay while measuring the impact on bay wildlife. East coast states other than Virginia do not allow menhaden reduction fishing in their states waters and what is Virginia's justification not to follow what other states have determined?

Categories: Menhaden 2 Auto Replied

I am writing to express my deep concerns about the status of our fragile ecosystem in the oceans, bays, and rivers. We have been allowing commercial vessels to come in and indiscriminately destroy what has been a thriving ecosystem.

These menhaden are the foundation of this ecosystem and they are food for natural predators such as whales, tuna, striped bass, bluefish, drum, etc. When we remove the food source we impact all of these species negatively as well. In addition, when these massive nets come into harvest huge quantities of these fish, they also capture and kill the predatory species that are actively feeding on the menhaden- resulting in thousands of dead bycatch discarded.

Not to mention that menhaden are filter feeders and are constantly cleaning our waterways.

I believe we are at crisis levels here; I see it first hand on the water multiple days a week. We are quickly making our oceans a desert and we need to stop all commercial harvesting of menhaden now. Thank you for your consideration.

Sincerely,
Paul Nugent

Categories: Menhaden 2 Auto Replied

Dear Commission Members,

I am writing to you from Connecticut, where I live along the beautiful shoreline of Long Island Sound.

A concerning observation that our area has identified is the lack of menhaden fish in our waters this summer. The impact of this had been devastating to our seabirds, in particular the Osprey, who depend on this food source during the summer in New England. Of the Osprey nests that have cameras, a large majority of the young Osprey starved to death this season. This has been extremely concerning and difficult to observe. Heartbreaking.

The menhaden is considered one of the most important fish in the sea due to its place in so many food chains, and as you are well aware these essential fish originate in the Virginia/Maryland coastline and come up north during the warmer weather.

The overfishing in your Virginia/Maryland waters is the probably cause of this decline of this essential food source for our wildlife. In particular Omega Protein.

THIS HAS TO STOP. PLEASE ACT TO PLACE LIMITS on the fishing for the next season, in tandem with the proposed studies regarding the decline in menhaden.

Any delay in implementing these limits will have a devastating and maybe irreversible impact on these majestic birds - Osprey.

I am also confused when I heard that that status of a federally protected bird like the Osprey is not taken into account when managing fishing numbers. This does not seem to align with the spirit of federal protections???

I have also sent this email on to Gov. Spanberger to ensure her office is aware of this urgent issue.

I thank you for your consideration - please do the right thing.

Sincerely,
Maureen Drouin

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Attn. James Boyle

Hello,
Thank you for your attention to my comment regarding Atlantic Menhaden Draft Addendum II.

My name is Jay Harwin, and I am a strong proponent of maximally restricting the menhaden fishery. This would include the Bay Reduction Fishery Option B4. I am also in favor of the Total Allowable Catch (TAC) being restricted as much as possible throughout the Atlantic Fishery.

I am a resident of the Connecticut shoreline, residing in Branford. I have been fortunate enough to live on Branford Harbor for the last 30 years. I've raised my children there, and feel enormous gratitude to have spent time almost every day engaged in activities on my local water.
I am a physician, an avid citizen scientist and a passionate observer of the local ecosystem. I am also an osprey steward with the CT Audubon Society, monitoring several local osprey nesting sites.

Menhaden (we always refer to them as bunker in our local waters!) have been a conspicuous presence through my life in Branford. By mid to late summers, the schools of mature individuals have been thick, remarkable, meandering masses of hundreds of thousands of individuals covering acres of our local harbors and estuaries. Sport fish have been active in our local waters. The schools are seen to "boil", or spill onto our local beaches when sport-fish are feeding, which was traditionally a daily occurrence. My children and I cherished the time of year when our evening paddles would lead us through this remarkable show of dense, mature menhaden literally filling our local waters.

Our local osprey population has successfully grown over the last several decades, and traditionally, almost every overhead osprey returning to its nest site was noted to be carrying a mature adult menhaden.

Everything changed in the 2024 season.
For the first time, spotting a menhaden school became rare. The change was frighteningly conspicuous and sudden, a profound change from 2023 to 2024.
In 2025, there were no menhaden visible in our local waters.
This 2026 season continued the disturbing trend. I inquired widely and heard of no mature menhaden schools throughout the CT shoreline or the vast, critical and recently healthy ecosystem of Long Island Sound.

There has been no successful sport fishing locally this season.
Our osprey population has struggled profoundly. You will hear a great number of anecdotal reports of this struggle. Our local Audubon scientists will quantify a bit more objectively the abrupt and coincident change in fledglings per nest. Our observers all witnessed the tragedy of starving nestlings, the grisly death of nestlings, starving adults, and the profound, sudden change in the frequency of food delivery to nest sites.

I am disappointed that despite these concerns for several years, the objective science to guide your decisions does not yet truly exist.

In the absence of objective data to guide your decisions, the only reasonable way to proceed is with thorough cost/benefit analysis.
If we make errors in our best subjective decisions, the risk of being overly restrictive is a socioeconomic cost that can be measured to corporate fisheries, and includes the unfortunate harm to the livelihoods of a modest number of employees and fishermen.

If we err by being too permissive with the TAC and the Bay Fishery, the risk would potentially be further devastation to an entire, profoundly complex Atlantic ecosystem.
Fish, shorebirds, raptors, crabs, shellfish, countless private fishing captains along the Atlantic seaboard all suffer.
This is a risk we simply cannot possibly tolerate. We must do everything possible to protect the vital ecosystem from any further possible disruption. There simply is no other responsible way forward.

Please do the only reasonable thing and protect the ecosystem that is giving us conspicuous and profound warnings that it is in trouble.

Please support the most restrictive TAC limits and the B4, most restrictive options in the Bay Reduction Fishery

Thank you for your attention to my comment.
I would be happy to provide any further feedback at any time

Jay Harwin

Subject: [External] Menhaden reduction please

Categories: Menhaden 2 Auto Replied

Hello-

I am writing to urge the ASMFC to reduce the catch limits on menhaden by 50% to allow this building block species to rebound to a healthier level. In Connecticut we have seen virtually no bait in our waters all year and only small amounts in 2025. This has caused all of our local fisheries to fall apart, with no sport fish staying in Long Island Sound since the middle of June
Pleas act to conserve these vital fish to protect the fishing public's interests

Thank you-

Bob Burger

Subject: [External] Atlantic Menhaden Draft Addendum II and 2027–2029 Catch Limits

Categories: Menhaden 2 Auto Replied

Hello my name is Lynn Moceri of Middle Township NJ.

As a member of the American Littoral Society, Surfrider Foundation and a citizen living along tidal water, I am writing about my concern of menhaden overfishing.
I don't need scientists to tell me the bunker population decline along the NJ coast has affected all manner of marine life that depend on this fish for feed.
With several osprey nests in view of my home, I can see for myself first the starvation of chicks and then the following year, the osprey just don't produce offspring at all. Out of a dozen nests I see while on the water, only one had chicks this year. After the dedicated efforts to restore the osprey population since the 1970's, it is a shame to be risking the health of this species yet again.

Please cut the industrial harvest cap by at least 50%, spread the
allowed harvest more evenly across the season, and make a substantial coast-wide catch reduction that meets ASMFC's ecosystem target.

I hope you will take the observations of the public into account when revising the rules.

Thanks you for reading,

Lynn Moceri

Time for studying is past. Almost every other State has banned or at least moved the reduction fleet offshore. Canadian companies shouldn't have the right to rape our natural resources. A complete moratorium for 5 years and then re evaluate the situation. A moratorium worked to bring back striped bass and now the starve bec there's not enough forage fish. Everything in the bays and ocean depends on menhaden population being healthy. Once plentiful in SW Florida they are now no existent because they were over harvested. Same will happen in the bay is this isn't stopped. Virginia commercial fisherman are going bankrupt trying to compete with farm raised inferior seafood flooding the market and the very food native fish need is being harvested to feed farmed fish. Not only not as healthy but we need to look out for American commercial seafood not foreign countries. Don't wait till everything is dead. Act now. A 50% reduction is just a stall tactic to buy foreign owned companies Time. Please put Americans first and stop this slaughtering of our essential natural resources. 🙏

For Consideration, I have a residence on Gwynn's Island and have some history with the water and environment surrounding that area. As the 50 years have passed and we see fewer fish and osprey, we ask ourselves what is going on? Well, it seems we have a clue, Maybe not an answer but certainly a clue. The loss of manhaden is certainly a part of the clue. Maybe not the entire answer but a clue. The depletion of fish and osprey would not even be an issue if manhaden were not fished out, so why can't a limit be imposed? I suggest, and recommend that this limit of 50% be imposed. This will allow the fishing and osprey to return and it can be a good guideline to see if there are improvements without stopping the menhaden fishing industry completely. If this measure does not pass, please provide a reason behind such a vote rather than just a 'no" vote. There is more to enjoying the Chesapeake Bay than oil and cosmetics.

Subject: [External] Atlantic Menhaden Action

Categories: Menhaden 2 Auto Replied

Hi ASMFC,

After years of kicking the can down the road, and doing virtually nothing about the overfishing of Atlantic Menhaden, the time has come for you to do your job of managing species for the future. Like many species that you have kick the can down the road to no helpful avail, it's time to do some about the Atlantic Menhaden. This is a unique species that fits into many economic and ecological scenarios. They are a food source for birds of prey, marine mammals and fish and humans. One of these factors seems to be destroying the species population.

Not only is the commercial sector destroying the population of Atlantic Menhaden in the Chesapeake Bay region but now they are moving out to other areas to decimate the population out there. The use of spotter planes is also helping in that feat.

We keep allowing Omega Protein, alongside its contracted fishing fleet company, **Ocean Harvesters to keep overfishing this species and making the birds and and the marine species suffer because of them.**

It's time for commonsense and the time for action is now. We see it in the Herring Industry with the River Herring being decimated in the ocean and the numbers haven't come back in the rivers. We need a reduction of 50% total and not just the Chesapeake Bay region but everywhere and a closure during the entire month of August for both the Striped Bass and Osprey to ensure a food source for them during that period. No rolling over quotes from one period to another. If they don't catch their quota, there is a reason for that and it's called Overfishing and will need to stop fishing if they meet their quota or face penalties. The Cap can be reviewed every three years and adjusted either way if need be. I also don't mind to see a reduction in the recreational sector. Do we really need to be taking 50 fish or a 5 gallon pail of them? No. If we want the commercial sector to take a cut, so should the recreational sector.

I know that there will be complaints about job loss but just think about the fact that the total loss of that fishery means the loss of all those jobs. What will they do if there are no Atlantic Menhaden? Maybe consider them onboard watchers to make sure the boats are doing everything by the book.

Thank You for taking time out of your busy schedule to read and document my opinion for the record. I know in the past the majority of the public wanted a more strict outcome for striped bass which the council disregarded but I am hoping they will take this more seriously.

Sincerely,

Roman Dudus

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear FMP Coordinator James Boyle and Members of the Commission,

I am writing as a concerned Virginia resident to express my support for Draft Addendum II and to urge the Commission to finally implement the strictest possible protections for Atlantic menhaden, particularly within the Chesapeake Bay.

Menhaden are the ecological foundation of our coastal ecosystem. Decades of intensive industrial reduction fishing have disrupted the local food web, leading to devastating impacts on wildlife that depend on them. We are currently witnessing an ecological crisis with our local osprey populations, where nesting success has plummeted due to a severe lack of food. Osprey chicks are starving to their death in their nests because industrial purse seines are clearing out the localized menhaden biomass.

To allow the menhaden population to fully restore and to protect critical predators like the osprey, I strongly urge the ASMFC to adopt the following measures:

- Implement a 50% reduction in the Chesapeake Bay reduction fishery harvest cap immediately.
- Establish strict seasonal closures during peak osprey nesting and migration seasons to prevent localized depletion.
- Prioritize ecosystem-based management that factors the nutritional needs of marine mammals, seabirds, and predatory fish into harvest quotas, rather than managing menhaden solely as a single-species commodity.

We cannot afford to wait for decades of further study while our osprey populations collapse. Please take decisive action now to restrict industrial overharvesting and restore the balance of the Chesapeake Bay.

Thank you for your time and your dedication to protecting our shared marine resources.

Sincerely,

Laura Mae, Chesapeake VA

Subject: [External] Stop the unsustainable harvest of Menhaden

Categories: Menhaden 2 Auto Replied

Dear ASMFC,

Atlantic Menhaden are being decimated by the factory fishing activities of a single Virginia-based company, Omega Protein, which is owned by the privately-held Canadian company, Cooke, Inc. The impact to the Chesapeake Bay is the destruction of the Bay's web of life. Menhaden are crucial to the survival of our Ospreys, who depend on this fish as their primary food. They are not able to provide Menhaden to their chicks as the Menhaden are no longer available due to Omega Protein overfishing. The chicks are starving. These actions are negatively impacting ospreys leading to a 14% annual decline in the Osprey population. It appears to be as devastating as DDT was in the past. More than 30% of adult female Ospreys are failing to breed. Other fish also are being negatively impacted, which in turn impacts local fishing. Allowing the destruction of the Chesapeake Bay food web must be stopped soon to stop the negative impacts from this one company. There are other ways of finding protein for humans and feed for cattle or salmon. Maryland outlawed the use of ocean-going purse seiners more than 50 years ago for good reasons. Unfortunately, all the Atlantic coastal states haven't outlawed purse seiners.

Besides osprey, this overfishing also affects prey items for Bald Eagle, Brown Pelican, Common Loon, and Royal Tern. Fish species affected by collapsing Menhaden numbers include ASMFC species of conservation concern: rockfish (overfished), bluefish (rebuilding), weakfish (depleted), and spiny dogfish (reproduction declining). Menhaden have been termed the most important fish in the sea.

You have the power to stop the unsustainable harvest of Menhaden and I respectfully ask that you do the right thing and stop Omega Protein from their current methods of harvesting Menhaden as they are currently doing. Letting one company get away with this destruction in order to profit harms the many.

Sincerely,
Pamela Langer

Subject: [External] Atlantic Menhaden Draft Addendum II Comments

Categories: Menhaden 2 Auto Replied

I support the following items for Draft Addendum II to Amendment 3 of the Atlantic Menhaden Interstate Fishery Management Plan.

Section 3.1 - Sub Option b4

Section 3.2.1 - Option B1

Section 3.2.2 - Underage Sub Option 1

Section 3.3 - Option B

Coastwide TAC - PAPER REDUCTIONS ARE NOT ACCEPTABLE. What is the point of reducing a percentage of a harvest quota that wasn't reached? Can we please use basic common sense. Unless we reduce the coastwide TAC by at least 30% - there is a 100% probability of overfishing. This should ideally be reduced to 50% or even more. Please prioritize the recreational economy over bad actors making food for animals.

Please see my further comments below:

It is clear Atlantic Menhaden has been grossly mismanaged, the effects of this are clear. As a full time fishing guide in Connecticut, I have visibly seen the amount of Menhaden go from harbors full of these important fish to hardly any at all. For the past three years, my son and I have not gone to our local salt marsh to net a few menhaden, attach them to a circle hook, and virtually guarantee a bite from a striped bass for my enthusiastic son. There are no Menhaden there. Not only does my now 6-year-old son, probably not remember those great moments from when he was 3, but we may never have them again. Not to mention the impact on my professional income as a guide. ASMFC has impacted my ability to make a living through this blunder in Menhaden management, compounded by equally grievous blunders in striped bass management and pretty much any other fish that falls under your purview.

There's no other way to describe this but borderline criminal, you are destroying our fisheries by prioritizing bad actors who have no concern for keeping this fishery sustainable. Do something now, for my son, and so I can continue to do what I love and earn a living SUSTAINABLY as a professional fly fishing guide.

I fully support a 50% reduction in the harvesting of Menhaden. I believe that such reduction would help the Stripe bass population and other species. I would support a five year reduction.

Omega Protein Economic Impact in Lancaster County

Commercial fishing and aquaculture are heritage industries in Lancaster County. As such, they remain an economic priority. In fact, recent evidence points to a resurgence in commercial fishing and aquaculture activity in Lancaster. This is primarily due decades-long state and local efforts to preserve and restore the Chesapeake Bay.

Working waterfront and water-dependent industries are historically the lifeblood of Lancaster County, and the region's economy. They remain a top economic and workforce development priority for Lancaster County and GoVirginia Region 6. Many of the projects funded through the Virginia Growth & Opportunity Fund are directly related to supporting these industries and their workforce.

Lancaster County's comprehensive and economic strategic plans specifically call for the preservation of working waterfronts and the growth of the water dependent industries they support. Lancaster County's efforts to grow its workforce by 1,000

persons by 2035 are directly tied to the growth of these industries.

Workforce Impact

Between the two companies, Omega Protein and Ocean Harvesters, they directly employ 260 personnel, of which 73 are residents of Lancaster County.
Annual payroll/benefits of over $29 million to these Omega and Ocean Harvesters employees, of which $12 million of goes to Lancaster County residents.
A majority of senior leadership resides in Lancaster County
-VP Sales (Nick Sterrett)
-Sr. Dir. Refined Oil (Jane Crowther)
-Dir. of Environmental Compliance (Hannah Smith Long)
-Production Manager (Sonny Abbott)
-Vessel Manager (Auston Robbins)
-Resident Project Engineer (Donald Blue)
-Captains/Spotters (Allen Hinson, Lee Robbins, Roger Smith, Michael Stevens)
100% of employees are US Citizens; no use of H2B migrant labor
-Most are multigenerational going back 5-6 generations
-Workforce is 52% African American
-Fishermen on vessels are organized under the United Food and Commercial Workers (UFCW) Union, Local 400
Indirectly employ over 250 others through service providers, contractors, construction, logistics, etc.

Local Business Impact

Over the past three years (2023-2025) Omega have directly spent $5,907,665 million with various businesses or charities in Lancaster County leading to an estimated indirect economic impact of over $11 million.

Consider this quote from Margaret Mead: "It was not until we saw a picture of the earth, from the moon, that we realized how small and how helpless this planet is - something that we must hold in our arms and care for."

In the Chesapeake Bay, Osprey chicks are starving and many adult pairs are not even attempting to nest. This is due to the depletion of their principal food, the Atlantic Menhaden, by the factory fishing activities of a single Virginia-based company, Omega Protein, which is owned by the privately-held Canadian company, Cooke, Inc.

Please stop this unsustainable harvest.

Subject: [External] Supporting complete closure of the reduction harvest of menhaden

Categories: Menhaden 2 Auto Replied

Dear Atlantic States Marine Fisheries Commission:

I write as a resident of the Chesapeake Bay watershed, a birder, and a veterinarian in support of the closure of the menhaden fishery.

It's painful to watch osprey chicks starve in the nest because their parents can not find enough food to sustain their offspring while menhaden are being harvested by thousands of metric tons for the reduction fishery. Our own Maryland watermen cannot find enough menhaden for use as bait.

We do have alternative sources of protein for pet and agricultural animal diets that do not depend on menhaden. Insect protein- based animal feeds are increasingly available to supply this market - but ospreys do not have an alternative source of food for their young.

Please close the menhaden reduction fishery.

Sincerely,
Waiva Worthley

The Menhaden fish population has plummeted due to overfishing and there needs to be a ban on fishing them to repopulate their numbers successfully.

Our osprey keep track of what is going on in our waters. Osprey populations have dropped tremendously due to the lowered menhaden population from overfishing. The osprey is a vital indication of clean water and abundant fish population and helps keep aquatic ecosystems healthy.

We need ospreys, clean water, and abundant fish. Regulation of fishing means some control of how much fishermen can fish without destroying their populations totally and that way the imposed fishing regulations help to continue the industry while keeping our waters clean and healthy.

Thank you,

Camille Woodbury

To whom it may concern,

I am concerned about the declining osprey population in Maryland. I have recently learned that the overfishing of menhaden in coastal waters and the bay are a big part of the problem. I support a closure of the rendition harvest or at least a 50% harvest cut for 2027. I also support spacing the harvest equally over May through November. The osprey population was growing so well after the use of DDT was banned in 1972. It's a shame that overfishing might cause it to reverse the growth we've had since then.

I write to express my strong concerns over the dramatic crash in Osprey breeding success in the Chesapeake Bay due to industrial fishing of Menhaden. I am a resident of Maryland that is a birder.
My first choice would be for ASMFC to act to close the industrial fishing responsible for 70% of the take coast-wide. If they are unwilling to do that, I would insist on at least a 50% reduction in current rendition harvests in Virginia. I would also strongly support spacing the harvest equally over May through November as proposed in Option B2.
I note that spreading out the Bay harvest will do little to assist the Osprey as when the Ospreys are breeding, there are already too few Menhaden in the Bay to support successful reproduction. **It is best to implement a complete closure of all harvest for rendering.**
Thank you for considering my concerns and recommendations.

Dear ASFMC, I'm a professor of biological sciences at UMBC where I teach and do research in ecology and conservation. I also happen to go fishing a lot in my kayak on the Chesapeake, including in the Severn and nearby tributaries. The decline in striped bass in recent years is very discouraging for me both as a fisher and as an ecologist. The overharvesting of menhaden is one of the worst environmental disasters that I am aware of in recent years on the East Coast. Please vastly constrain or put a moratorium on menhaden harvest so that this crucial part of the food chain is restored to the Chesapeake and other nearby waters.

Sincerely, Kevin Omland.

Categories: Menhaden 2 Auto Replied

I write as a concerned resident of Maryland who is appalled at the sudden decline in Osprey reproduction, which is directly tied to the overfishing of Menhaden by Omega Protein, which uses a fleet of 10 vessels, including large purse seiners, to harvest 70% of the Bay's Menhaden. (Cooke Inc. of Canada purchased the company in 2017 for $500 million.)

I urge you to initiate long-overdue restrictions on this Virginia-based slaughter that also affects prey fish for Bald Eagles, Brown Pelicans, Common Loons, and Royal Terns. Other fish species affected by collapsing Menhaden numbers include ASMFC species of conservation concern: rockfish (overfished), bluefish (rebuilding), weakfish (depleted), and spiny dogfish (reproduction declining). But it's the Menhaden that Ospreys depend on to feed their chicks. Osprey fledging success for 70% of Bay Ospreys has dropped to a frighteningly low 0.25 per nesting pair in 2026, which is well below the ideal replacement level of 1.15 and even lower than the worst years of DDT-crashed reproduction in the 1960s. This data, from biologists surveying 900 nesting pairs throughout Maryland and Virginia Bay waters, reflects *drops from 0.5 to 0.35 in the last two years alone. This equates to an alarming Osprey decline of 14% a year.* Similar declines are being observed in Delaware, New Jersey, Connecticut, Rhode Island, and Massachusetts as Omega Protein and their harvesting affiliates scoop millions of Menhaden from the Bay and Atlantic Ocean.

Please close the harvest until Osprey populations recover, and after that, impose and enforce strict harvest restrictions of at least 50% in Virginia. Thank you.

Subject: [External] URGENT: Ospreys starve as Menhaden are over fished

Categories: Menhaden 2 Auto Replied

Dear Maryland Department of Natural Resources and Potomac River Fisheries Commission:

I am writing to urge you to take immediate action to protect Atlantic Menhaden in the Chesapeake Bay and its tributaries. Menhaden are a critical food source for Chesapeake Bay Ospreys, yet their availability has declined dramatically. Biologists are reporting an alarming collapse in Osprey reproduction, with chicks starving because their parents cannot find enough of these nutrient-rich fish. Menhaden once made up approximately 75% of the Osprey diet in key areas of the Bay; today, that figure has reportedly fallen below 30%. The consequences extend beyond Ospreys—Menhaden are a vital part of the Chesapeake food web, supporting Bald Eagles, Brown Pelicans, loons, terns, rockfish, bluefish, and many other species.

I respectfully ask Maryland DNR and the Potomac River Fisheries Commission to use every regulatory and interstate avenue available to advocate for an end to industrial Menhaden harvesting for reduction purposes in the Chesapeake Bay and for stronger coastwide protections. If a complete closure cannot be achieved, please support substantial reductions in industrial harvest levels and measures that prioritize the ecological needs of the Bay. We cannot continue removing millions of these essential forage fish while Osprey chicks starve and the Chesapeake ecosystem suffers. **Please act now to protect the Menhaden, the Ospreys, and the future of the Chesapeake Bay.**

Sincerely,

Valerie Stutman Portney

We are experiencing an ecological disaster affecting both fish and bird populations along the east coast of the United States due to Menhaden overfishing in the Chesapeake Bay. The main purpose of the overfishing is the production of fish oil. An immediate reduction of at least 50% of the allowed Chesapeake Bay Menhaden catch is needed. Since 75% of the Menhaden catch is allocated to the Chesapeake Bay, a 50% reduction still allocates 37.5% of the total catch to the Chesapeake Bay. Further reductions may be necessary in the future to restore both fish and bird populations that depend on Menhaden.

Subject: [External] Atlantic Menhaden Draft Addendum II

Categories: Menhaden 2 Auto Replied

Dear Members of the Atlantic Menhaden Management Board:

I am a 45-year-old Baltimore resident, bird lover, and nature enthusiast writing to urge you to take meaningful action to protect the Chesapeake Bay ecosystem by reducing the Chesapeake Bay Reduction Fishery Cap by 50 percent. I am not a fisheries scientist, and I do not make my living from the Bay. I understand that people do, and that decisions about commercial fishing affect real workers and communities. But I also know what it means to live near the Chesapeake and to see its wildlife as part of the fabric of this place.

One of my favorite sights is an Osprey perched high above Fort McHenry in Baltimore. An Osprey is one of those birds that can make you stop what you are doing and just watch. They are enormous and graceful at the same time. Seeing one hover over the water and then plunge after a fish is thrilling no matter how many times you have seen it.

That is why it is so disturbing to learn that a bird that appears so powerful is struggling simply to find enough food to successfully raise its young. Researchers have documented serious reproductive failures among Ospreys in parts of the Chesapeake Bay, including chicks dying from starvation and reproductive rates falling below the level needed to sustain populations.

Virginia's reduction fishery, operated by Ocean Harvesters and supplying Omega Protein, is the only one of its kind operating inside the Chesapeake Bay. I recognize that scientists are still working to understand exactly how local menhaden abundance, commercial harvest, and other environmental factors interact. But scientific uncertainty should not become an excuse for doing nothing when the warning signs are this serious.

That is what the precautionary principle is for.

We have been here before with Ospreys. Their populations were devastated by DDT in the 20th century. We changed course, and these remarkable birds recovered. It would be heartbreaking to watch that recovery unravel because we were unwilling to leave enough food in the water for them.

Please adopt the strongest conservation option before you: reduce the Chesapeake Bay Reduction Fishery Cap by 50 percent and spread the allowable harvest across the fishing season so that enormous quantities of menhaden are not removed during critical periods for wildlife.

I want someone standing at Fort McHenry 20 or 30 years from now to be able to look up and see an Osprey perched above the water—and to feel the same awe I do today.

We know enough to act. Please do so.

Sincerely,
Nikki Gamer

Please do whatever has to be done to save the wildlife specifically the Osprey population. When I read what is happening to the Ospreys it made me sick at heart. It is disgraceful and sad that their chicks are starving! This is similar to what happened to the Eagles! The Ospreys need to be able to access a supply of Menhaden for producing and maintaining healthy chicks. Please extremely limit whatever greed driven actions are contributing to this deplorable situation , including the chemical industry's contribution to climate change. Biological diversity is important for now and our future!

I am a professional ecologist for over 40 years, grew up on the south fork of Long Island an have been president of the New York Marine Rescue Center for over 25 years. The commercial menhaden catch has to be reduced or eliminated. As a professional, I have witnessed the drastic reductions in fisheries dependant on this resource. We have spent decades improving ocean/bay water quality, have seen the return of ceataceans and Ospreys to our waters only to see massive factory ships in our bays, offshore limiting the forage species needed to continue the species restoration we have worked so hard for these many years. Why when other protein sources are available would your commission continue these catch policies that directly oppose all the restoration successes we have made to date. Thank you for the opportunity to comment. Charles Bowman

Recommend Reduction = B4, Quota Periods = B2. I'm an avid fisherman who used to fish more than once a week on the Potomac from Ragged Point - Piney Point and all the way downstream to Pt Lookout - Smith Point Lighthouse. Last couple of years it is very noticeable the lack of menhaden in the Potomac and the corresponding lack of Stripers. And if I catch any Striper before the fall migration, the fish are undernutrition and hardly worth keeping. Also, we used to have 4-6 Ospreys on our creek off my dock and this year we had just 2. They did manage to have one chick but it didn't make it to maturity (don't know what happened to it). Maybe the lack of menhaden isn't the only reason it may no longer be worth sport fishing but it is definitely a major cause.

Good afternoon, my name is Nicholas Molteg and I am an avid fisherman and outdoorsman from NJ. I fish the raritan bay mostly and I have noticed a drastic reduction in bunker. 10 years ago I used to see schools all over the bay and birds working bait everywhere. I'm on the water at least once a week from April through November and I haven't seen a school of adult bunker inside the bay in at least 3 years. It's scary to think what this over fishing is doing the our ecosystem. The information on osprey chicks and populations suffering from starvation is enough for me to support a reduction in the menhaden fishery alone. I hope you will act responsibly and save this valuable resource for the health of our coastal ecosystems as well as for the next generations of young fishermen and women as well as wildlife enthusiasts. Thank you for your consideration in the matter.

Hello - I am a resident of NJ , loving along the Jersey shore in Brick,NJ all of my adult life . Being a nature lover I have always observed the many varied shorebirds , including the osprey ,and remember its plight back in the 70s due to the use of DDT and its remarkable comeback . This summer , before I was even aware there was a problem , I noticed there seemed to be fewer Osprey . When I came to my attention there there was a crisis due to the depletion of menhaden , I increased my observation and have to say I've only seen a very small amount and only one nest with a chick . Discovering the issue of the overfishing of menhaden I implore you to reduce the amount t of fishing to help restore the osprey population . It would be such a shame to lose these great fisher birds esp coming back from near extinction in the 70s - there needs to be a cap on how much menhaden can be taken from our waters
Thank you for listening

I beg you to implement the 50% cap. The osprey who depend on menhaden are starving. On the principle of Occam's Razor - the simplest explanation is usually correct - there must not be enough fish for them to eat. We must take fewer. Please choose responsible stewardship over profit.

I strongly support a minimum 50% menhaden catch reduction, if not more. A healthy, stocked menhaden population is critical to the short and long term survival of many saltwater species throughout the Mid-Atlantic waters as well as various bird species such as Osprey.

I've seen a significant decline in menhaden over the past few years, action must be taken to address this issue.

I live in Reedville and see the Menhaden boat going out and coming back in. At times I count 6 boats coming in in one day. They are now running all year around and don't seem to be any limit on them. Their fishing needs to be at cut at least by 50% or more or shut down completely. The 100 or so jobs supposedly that the Omega factory employs is nothing compared to the fisherman and charter boats staff that have been cut due to the scarcity of fish on the bay. We hardly see any ospreys anymore. Years ago we use to see some swarms of Menhadens but not anymore.
Reedville will prosper much better without the Omega factory and doesn't need the Omega factory to survive. More jobs and businesses will appear in Reedville without the Omega factory.

As a person of faith and I am a sincere person of faith, a retired ordained Deacon in the Episcopal Church in Connecticut and a member of the Third Order of Saint Francis (Episcopal). I believe that we all are called to be care for creation. It is my understanding that the The Atlantic States Marine Fisheries Commission is considering changes to the amount of menhaden that can be harvested from the Chesapeake Bay. As a person of faith, I am urging the commission to reduce the fishery cap by 50 percent, a precautionary measure to ensure that menhaden, a key foundation fish and a prime food source for Ospreys, are not put in even greater jeopardy.Last year Connecticut Audubon's Osprey Nation recorded its lowest breeding success since the statewide community science program launched in 2014 to monitor the birds. This year is looking even worse. Osprey and other species that rely on menhaden do not have years longer to wait. Decisive action is needed now. I ask you to support this change in order to protect creation.

As a long time resident on the Potomac River I have witnessed decline of the fish population and most recently the absense of the beloved Osprey. I'm not a scientist but it doesn't take a scientist to figure out what the problem is. The change in our water's ecosystem is devastating, tragic and very frustrating! And it is fixable! It will take time to repair the damage but the powers that be MUST keep politics out of the matter and do what is right for our fragile Chesapeake Bay ecosystem by drastically limiting the amount of allowable catch of the Menhaden. This is a fight for the survival of the "the most important fish in the sea", the lifeblood of the Bay's ecosystem! In the short run I support Amendment II !!! But That's NOT Enough! Far more must be done! This isn't a political matter! It's a choice between what is right and what is wrong! Allowing 1 company to depleat the Bay and Atlantic Ocean of an essential natural resource for financial gain or choosing to take step to protect our waters for long after we are gone!

Get the MANHADEN fishing out of the Chesapeake Bay and off the coast 3 miles out in Federal Waters. They are raping the bay and destroying a National Treasure. We were recreation fishing on our 9/16/2026 and there were no less than five commercial manhaden boats with spotter planes raping the bay. Did not catch one keeper fish all day! Wake up and protect the Chesapeake Bay from a foreign owned company!

I support a reduction of at least 50 % of Menhaden catch with observers on board of vessels. I work as a nurse and there are checks on us- why not on a Canadian fishing industry?
Our Virginia nursery is being depleted of the very important Menhaden. This fish is esssential to Osprey and mammals, wildlife and fish. Menhaden is not essential to dog food!
I am shocked that this board has let this go on that long!

I support fisheries management in the Chesapeake Bay that is firmly based on the best available science and considers the health of the entire ecosystem. Atlantic menhaden are a critical forage species for striped bass, birds, and other wildlife. I urge the Commission to prohibit industrial-scale commercial menhaden fishing within the Chesapeake Bay, consistent with the restrictions adopted by the other Chesapeake Bay states. Virginia should not remain the exception. Commercial harvest can continue in appropriate ocean waters, but the Bay itself should be protected as an essential nursery and feeding area. Please prioritize the Bay's long-term ecological health over short-term commercial interests.

A Legacy Story.

In the 1870's a commercial fishery began operating in the Chesapeake Bay.

Seven generations of watermen have depended on a productive menhaden harvest to support their families.

Those watermen are crabbers, and they currently number in the thousands.

Both VMRC and MDNR acknowledge a 90% drop in the menhaden bait harvest over the past decade.

The cost to crabbers for menhaden has more than doubled in the same time period.

The Chesapeake is categorized by ASMFC as the primary nursery for the Atlantic Menhaden biomass.

We ask you to prioritize it as a bait fishery and manage it for abundance, to the benefit of commercial watermen in the

Chesapeake and across the Atlantic Seaboard.

Thank you.

Cutting Omega to a 50% reductions is too small. Omega and Ocean Harvesters should be pushed outside the 3 mile limit along the entire Atlantic Coast. I have fished the waters of the Chesapeake Bay and Mid Atlantic for over 60 years and I've seen the change for the worse. There used be abundant schools of menhaden being chased by predator fish all the time and regardless of the time of year. Those days are gone and don't even try to tell me that my eyes are lying. You can see what no longer exist. For too many years Omega and Ocean Harvesters have taken a Public Resource and made a profit out of it. Based upon that business model what legal duty of stewardship do they currently have to do no harm to the ecosystem they continue to exploit to the significant detriment to others that rely on a functioning and healthy ecosystem. When a developer buys private land they have a legal duty to pays all the fees associated with the transfer of ownership. Then why is Omega allowed to harvest a public resource and have no legal duty to pay a fee for the transfer of ownership of these fish. When the developer decides to build on the property then they are held to the standards and requirements to Do No Harm to the local community. Again I ask then why is Omega allowed to develop these fish without any standards of Do No Harm to the local/regional community and this instance that is the Chesapeake Bay and the species that are supported by a healthy population of menhaden. NO FOOD EQUALS NO FISH. It's basic Biology 101. In times of famine reproduction rates fall. It's built-in fail safe biomechanical response to preserve the breeding stock of the species from the stress of famine. My eyes don't lie and I can't see what is not there. Unless there is a change in how the menhaden are managed it will only get worse.

I support the proposed Draft Addendum II. I kayak regularly in the Chesapeake Bay area; seeing osprey in their nests, feeding their young is an amazing experience. Menhaden are a crucial food source for osprey. The current 'pulse fishing' practices can locally deplete schools just when osprey need them most. Lowering menhaden harvest caps while spreading out the harvest season throughout the year will help ensure there is enough of this keystone species to support both the osprey and other wildlife, as well as Bay area fishermen's livelihoods.

I am a New Jersey resident, recreational fisherman, and boater who spends a significant amount of time on our coastal waters. I am on the water approximately once or twice every week during the boating season, and I have watched the condition of our local marine environment closely for years.

What I have observed in recent seasons is deeply concerning.

There has been a dramatic reduction in the menhaden, or bunker, that I see in New Jersey waters. At the same time, I have observed substantially fewer of the predators that depend upon this forage base, particularly striped bass, dolphins, and whales. I recognize that personal observations cannot establish scientific causation, and that many factors affect the distribution and abundance of these species. But when people who spend hundreds of hours a year on the water repeatedly observe these changes occurring together, those observations should not simply be dismissed because a coastwide assessment does not detect localized depletion.

That distinction is particularly important because ASMFC itself acknowledges that the current stock assessment evaluates Atlantic menhaden on a coastwide basis and cannot determine stock status at smaller regional scales. The coastwide stock is

presently classified as not overfished and not experiencing overfishing, but the most recent ecological reference point assessment also found fishing mortality above the ERP target and fecundity below the ERP target. ASMFC consequently reduced the 2026 TAC by 20%, and its own technical analysis indicates that reductions of 50% or more would be necessary to lower the probability of fishing mortality remaining above the ERP target.

That is exactly why I believe a precautionary approach is warranted.

I strongly support the maximum available reduction in the Chesapeake Bay reduction-fishery cap under Draft Addendum II. However, I am equally concerned that protecting the Chesapeake without meaningfully reducing overall fishing pressure could simply redistribute harvest into the Atlantic Ocean and other coastal areas.

Please do not solve a Chesapeake Bay problem by moving fishing pressure somewhere else.

New Jersey cannot become the release valve for restrictions imposed elsewhere.

ASMFC's own Draft Addendum recognizes the possibility of localized effects and acknowledges that recent concentrations of reduction harvest may affect menhaden availability to other fisheries and predators. The document notes that in 2023 and 2024 more than half of Chesapeake Bay reduction-fishery landings occurred during a six-week period, and the Commission is considering these measures specifically because localized availability matters even when the coastwide population may appear sustainable.

That same principle needs to apply beyond the Chesapeake Bay.

I urge the Atlantic Menhaden Management Board to substantially reduce coastwide allowable harvest and to establish protections that prevent fishing effort displaced from the Chesapeake from simply concentrating in New Jersey or elsewhere along the coast. I would also urge New Jersey representatives on the Board to protect menhaden abundance in New Jersey waters specifically, including consideration of substantial reductions in harvest where necessary to maintain adequate forage.

For those of us who fish and boat here, menhaden are not simply another commercially harvested species. They are one of the foundations of the coastal food web.

Striped bass, bluefish and numerous other predatory fish depend heavily upon this forage. Marine mammals and seabirds also utilize menhaden. ASMFC's ecological reference point system itself recognizes menhaden's importance as forage and specifically incorporates the needs of striped bass into management.

There is also a significant economic issue that should not be overlooked.

Personally, I spend tens of thousands of dollars every year participating in recreational fishing and boating. That spending supports marinas, fuel docks, tackle shops, marine mechanics, boat dealers, restaurants and other coastal businesses. I have already reduced the number of fishing trips I take and the number of guests I bring onto the water because the quality of the fishery has declined.

I am one person, but recreational fishing and boating represent an enormous coastal economy. Menhaden should therefore not be valued solely according to the pounds that can be commercially landed. Their greatest economic and ecological value may be realized by leaving substantially more of them in the water as forage supporting the rest of the ecosystem.

Once a forage base is seriously diminished locally, rebuilding the ecosystem that depends upon it is much harder than protecting it in the first place.

I therefore ask the Board to take the strongest precautionary action available under Draft Addendum II, including the maximum reduction in the Chesapeake Bay reduction-fishery cap, while also taking action on the coastwide TAC and future management measures so that harvest pressure is genuinely reduced rather than geographically redistributed.

Protecting menhaden in the Chesapeake while allowing depletion to occur off New Jersey is not comprehensive ecosystem management. Atlantic menhaden are a coastwide resource, and their management needs to reflect their coastwide ecological importance.

Please protect this forage base before the loss becomes something that is obvious in a stock assessment only after fishermen, boaters and coastal communities have been watching it disappear for years.

Thank you for considering my comments.

To whom it concerns,
It is clear the Omega 3 commercial fishing vessels are rapidly depleting the stock of this vital species. We are seeing very low numbers in the north east . The fish that are there are juvenile in size. Many species of marine life depend on Menhaden and other bait fish as their source of food. It would be a travesty if Menhaden are completely depleted. The marine eco system will be devastated.

Respectfully Sean Elliott

The Chesapeake Bay Foundation has repeatedly called for a closure of the Virginia rendition fishing. CBF notes how industrial fishing continues to empty the Chesapeake Bay and Virginia must pause Menhaden reduction fishing in the Bay.
The Menhaden industry has not once offered public support for funding state Menhaden research. The continued political pressure from Omega Protein and their McGuireWoods lobbyists to delay science is damning—and should concern everyone who cares about the Bay.
Meanwhile, Chesapeake Bay watermen are seeing Menhaden catches plummet, blue crab fishermen are spending more on bait, and Osprey chicks are starving to death.
But if the ASMFC is unwilling to act to close the industrial fishery responsible for 70% of the take coast-wide, join CBF, other conservationists, and me in insisting on at least a 50% reduction in current rendition harvests in Virginia. Also support spacing harvest equally over May through November as proposed in Option B2.
But note that spreading out the Bay harvest will do little to assist the Osprey as when the Ospreys are breeding, there are already too few Menhaden in the Bay to support successful reproduction. It is best to call for complete closure of all harvest for rendering.

The osprey population in the severn river watershed is collapsing these past couple of years. Let's err on the side of caution and restrict menhaden fishing and see if this helps. One of the theories about the collapse is the reduction of the right size of prey, and this may very well be linked to overfishing of menhaden.

It's time to finally limit this fishery for the widespread effect it has on the native foraging species that hunt the Chesapeakes waters. The capture of the bulk of biomass of menhaden wiping out the majority of the migration must stop or be greatly reduced. I support the 50% harvest reduction but support lawmakers to increase the harvest amounts and methods of harvest considering migratory patterns for the optimum time for harvest closures. Our current president is making it more difficult to protect our natural resources. It's time we fight back and reclaim our healthy Earth

Born and raised in Virginia, we should all realize how vital the Bay is ..an ecosystem, that depends on its own health of clean water and diversity to sustain a multitude of species in and out of the water…Weren't things like this going on in the 70 80 into the 90, over harvesting, pollution, and weren't regulations put in place to bring back oysters, fish and Eagles …oh and Osprey too I believe … Many living things depend on the Bays health. Stop allowing the overfishing of menhaden.. for the sake of us all stop corporate greed.

Hello,

I am very concerned about the reduction of fishery cap. This will greatly impact the number of available fish for the rest of the ecosystem. We have already seen a huge decline in the successful chick rate in our top level predator, the osprey. This means the rest of the food chain is already impacted. We need stronger regulations to increase wild fish populations.
Thank you,
Sarah

I think it is needed to ban menhaden industrial menhaden reduction industry from Virginia Waters. The reduction industry has greatly reduced menhaden numbers everywhere they have existed. The numbers are only. A few percent of 1970 levels.

Menhaden feed whales, bluefish and drum in addition to osprey which are starving. Bluefish and drum are reducing crab, herring and shad because there are not enough menhaden.

I support the strongest reduction in the reduction industry in Virginia Waters. If the best option is reducing the catch limit by half and moving the fishing away from osprey nesting season, that is helpful. But we should not be protecting this foreign industry at the cost of so much wildlife and Virginia economy. If 300 low paid jobs oh menhaden vacuumers is the issue, then let's hire them to plant trees and build oyster reefs. There is no need to protect the reduction industry.

Menhaden are such a critical food fish for so many bird species as well as larger fish species throughout New England (Maine to New York). It is critical that this species not be overfished or depleted far to the south in Maryland. Of particular concern in Connecticut is the availability of Menhaden for our struggling Osprey population. The numbers of Osprey and their offspring continue to decline from year to year.

Please consider the big picture and implement the 50% reduction in the Bay Cap, and follow option 2B for how the catch is distributed in amounts across time.

Thank you for listening.

I fully support the proposed restrictions made by the Chesapeake Bay Foundation to limit the harvesting of menhaden from the Chesapeake Bay both by lowering the catch amount and time-of-year restrictions. We are losing our beloved ospreys to overfishing of this important forage fish not to mention the deleterious effects upon the game fish in the Bay that are dependent upon menhaden.

My husband and I live near the Chesapeake Bay in Virginia Beach, Virginia. We are both avid nature photographers and have been photographing osprey and osprey nests at First Landing State Park and Pleasure House Point Natural Area for the last ten years. We've noticed a sharp decline in the number of osprey and in recent years, where we used to see nests with chicks being fed by adult osprey, the nests are eerily empty.

We strongly support the Atlantic Menhaden Draft Addendum II.

Hello. I'm a wildlife photographer and content creator who documents the Jersey Shore. Fish were my first nature interest at a young age. I surveyed my local streams and creeks by bike with a net and bucket and was encouraged by two local scientists who worked for the NJDEP to pursue math and science and continue exploring the environment. I later began to focus on birds too. Ospreys have always been easy to spot in coastal NJ, but after a devastating two years with nest productivity at levels lower than the DDT era, I fear for the species. This summer, a juvenile osprey was sitting at a local lake unable to fly. It was weakened by starvation and died a couple days later. The local wildlife refuge used to have many active nests. This year, by the end of the season, many were empty from failure. Ospreys are carrying back fish that are tiny and barely a meal to feed chicks. The bunker are not there. When the most important fish in the sea is missing, the species above on the food chain begin to crash. If we don't take action now to limit the total catch, it will be too late. We don't have time for longterm scientific studies. Species are starving now. Bunker populations need a chance to rebound. Rachel Carson warned us of a silent spring. The bunker are warning us of a barren beach.

Hello, I live in Stamford, CT and this summer (2026) I have absolutely witnessed fewer Ospreys in the area. Perhaps not coincidentally, I have seen ZERO schools of bunker in Westcott Cove where I routinely paddle. This is a stunning observation, as I typically spend summers surrounded by schools on bunker. To see NONE for entire summer is shocking and upsetting to say the least. The “downstream” effects of over fishing is environmental collapse and Ospreys, on this case, are the canaries in the coal mine. Protecting and stewardship is paramount!

Menhaden are the most important part of the food chain. In New Jersey, they have had a very poor year in 2026. Ospreys were on the verge of recovery in 2025. There were so many empty nest and vacated nests in 2026 that it was the worst Osprey breeding season in a long time. The government of the state of Virginia has for too long been beholden to the commercial Menhaden fishery. Reduce the fishery quota on all fronts rather than shifting it from one area to another.

We must balance the needs for both sides: 1) the ecological needs for the mehhaden, and 2) jobs and products that result from harvesting the menhaden. Neither side should completely control this. It has to be a balance between the two sides. Both sides must live in harmony, sharing this important resource.

Enough of the planes spotting the schools of menhaden. The trawlers have such an advantage and the by catch is such a total waste of resources. Watching the trawlers in the Rappahaock River taking everything as the planes go on to direct more of the fleet to destroy more crab pots and sport fish and watching the dead by catch float on the surface is beyond words. Reduce the quota and restrict or ban the use of spotter planes.

It is my opinion that the decrease of menhaden on our Atlantic coast is hurting the recreational fishery. In the last two years our fishery has been declining at a serious rate and I think it's directly related to a decrease in menhaden. It'sy understanding that these forage fish are being taken from our waters, processed and sent to Canada to feed Salmon in fish farm's. If that's true that doesn't seem fair to the Americans who rely on menhaden for their lively hood. Please put more restrictions on the harvesting of menhaden especially to foreign countries.

Please stop OMEGA protein from overharvesting Menhaden. I live on Stingray Point where the Rappahannock and Piankatank meet. The size of the Menhaden are 3- 4inches long and we have not seen a Striped Bass in the Fall in 3 years . State Senator Richard Stuart has over protected a small group of Harvesting fisherman. I need to committee to protect US (the recreational fisherman) from large corporations, selling our baitfish overseas. 4 of the local charter boats in Deltaville have sold out as there is no fish in the fall to support their business. No Rockfish = No paying customers to spend money shopping and buying supplies in Middlesex county

I don't feel it is right for Omega to take such large quantities of Baitfish so there is nothing for striped bass to eat except smaller striped bass , baby flounder and small Speckled trout . Our Bay area in front of our home is devoid of baitfish as we no longer see Gannets in the fall at P1 and P2 buoys on The Piankatank estuary .
I pay significant taxes to live on the water and feel a Canadian for profit Company (Omega) Ocean Harvesters has the right to steal our fish. Please limit their catch significantly NOW

I Stand with CBF and call on the ASMFC to approve conservation-minded reforms that better protect menhaden and support a healthy Chesapeake Bay ecosystem, including reducing the Bay Cap by 50 percent in 2027 and implementing quota periods to more effectively distribute reduction fishing pressure throughout the season. Specifically, CBF supports the following options in Draft Addendum II:

3.1 Chesapeake Bay Reduction Fishery Cap Amount: Support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.

3.2 Chesapeake Bay Cap Distribution: Support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. Also, support option B which establishes quota period overage payback and rollover of unused quota within a fishing year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

I am very concerned about what's happening with the Chesapeake Bay and wildlife. We need to do more to protect these vital habitats by reducing the human impact we have on the area directly and indirectly through the many things we do on land, in the air, and water that feed into these habitats. There is no second chance here. We need to act immediately to curtail our destructive behaviors and save what is left before it, too, is gone. We have been over fishing the menhaden and the Osprey are already suffering dramatically. We need to reduce the fishing allowed immediately to give these critical species a chance to survive.
I live alongside the Elizabeth river and near a few typically active osprey nests, that were completely empty this summer. This cannot continue. Protect the fish to give our birds a chance. Please. Reduce the fishing allowed to give our other beloved species a fighting chance to survive.

I am writing to express my serious concerns regarding the current harvest levels of Atlantic menhaden and their localized impact on the Chesapeake Bay ecosystem over the past decade. As a resident who frequently spends time on the water in the upper parts of the Bay, I have observed a troubling trend concerning our native raptor populations—specifically osprey and bald eagles—that rely heavily on menhaden as a primary food source.Over the last ten years, local researchers and community observers have documented declining nesting success and increased chick mortality among upper Bay ospreys. Menhaden are a vital, energy-dense nutrient source necessary for these birds to successfully rear their young. When industrial and commercial harvest levels deplete these localized schools, our apex predators are forced to rely on less nutritious alternative prey, leading to localized starvation in nests.While coastwide stock assessments may show that menhaden are not technically "overfished," a coastwide metric fails to account for the localized depletion happening right here in the cradle of the Atlantic population. The Atlantic States Marine Fisheries Commission (ASMFC) committed to Ecological Reference Points (ERPs) to manage this fishery with predators in mind. I urge the Board to fully honor that commitment by implementing stricter localized harvest caps within the Chesapeake Bay.Please prioritize the health of the entire food web and lower the harvest limits to ensure our raptors and the broader Bay ecosystem can recover and thrive.

On behalf of myself and Coal Kills Baltimore,

We are strongly in support of the proposed draft addendum that would reduce the Chesapeake Bay menhaden harvest cap by up to 50% and spread harvest more evenly throughout the season.

We all know, menhaden are a major forage fish, a critical food source for a wide range of predators, including striped bass, bluefish osprey, and other fish and wildlife. These predators are not only withdrawing but dying. The osprey population in our watershed is in sharp decline.

When large numbers of menhaden are harvested in concentrated areas during certain periods, the impacts may extend beyond the menhaden population itself. Changes in their availability can affect the larger food web and the species that depend on them.

As someone who personally uses Omega 3 supplements (not sourced from menhaden, but, rather anchovies, sardines, mackeral and herring) I appreciate one of the primary products and am sensitive to the needs of the industry that is

harvesting, also for livestock feed, bait, and whatever other uses.

We already are predicating an industry on the extermination of living things, acceptable, I suppose, when managed correctly, but when it endangers the interwoven web that keeps alive an entire ecosystem in the third-largest estuary in the world, we must recalibrate. These decisions must be based on research and science, not business first. If the balance is disturbed, species - and humanity - suffer permanent harms, even the threat of extinction.

We strongly side with Chespeake Legal Alliance and others in support of this draft addendum.

Sincerely,
John Scheinman, Olivia Yates

I am writing to express my strong support for Draft Addendum II to Amendment 3, specifically urging the Board to adopt robust measures to address localized depletion of Atlantic menhaden in the Chesapeake Bay. As the primary nursery ground for menhaden and a vital feeding area for striped bass, bluefish, and osprey, the Bay suffers when industrial reduction harvest is heavily concentrated in localized waters.

For too long, a Canadian company has been allowed to take way too large of a portion of the menhaden for non-essential products and profits. The Reedville fishermen will need financial help to shift jobs but the economic benefit to tourism and other fisheries will far outweigh their losses.

To meaningfully protect this critical habitat, I urge the Board to significantly lower the Chesapeake Bay reduction cap (by up to 50%), link the Bay cap directly to changes in the coastwide Total Allowable Catch (TAC), and establish seasonal quota periods to prevent heavy harvest concentration during peak summer months.

Precautionary management is vital to preserving the ecological integrity of the Chesapeake Bay, and I appreciate your commitment to strong marine stewardship.

Please support limits on the current over fishing of the menhaden fish as well as other species. The starvation of so many osprey young this season has been devastation and terrible to watch. Why isn't the status of a federally protected bird being taken into consideration when deciding on fishing limits? That seems to clash with the spirit of what federally protected means.
Thank you for doing the right thing,

I'm all for protecting our coastal waters from over-fishing, especially Bunkers. My question is how the Fishery Management will be able to enforce these new regulations. We've all witnessed Poachers from our Neighboring States, namely Maine and Massachusetts(the worst offenders). With the State of our Country being in such a crap condition, most Coast Guard assets are more involved with Drug enforcement, along with assisting illegal emigration patrolling & control. Even the Navy is over-extended so my question is Who's Left? Maritime enforcement for Fisheries is pretty low on the totem pole for having the ability to enforce ANY new quotas or Regulations that are decided upon. I wish the Commission all the best with bringing the base stocks of game fish & Bait fish back to healthy condition.

I have enjoyed the Chesapeake Bay and it's tributaries for more than 50 years. Over the last 15 to 20 years I've seen a significant decline in adult menhaden. Prior to this it was all too common to see miles of menhadden schools flashing on the surface as I headed out early in the morning. Today I'm lucky if a spot a single school of menhaden and in fact most times I do not. While fishing the Chesapeake Bay I noticed the large scale Menhadden boats wiith their huge nets encircle entire schools of menhadden along with game fish bi-catch. The use of this fishing technique, spotter planes and large industrial need to stop. It has proven unstainable and a severe detriment to every fish and crustation that feeds on these fish. Please end this in our bay. Thank you. Michael Mounie

Atlantic menhaden should be managed first and foremost as forage, not simply as a harvestable commodity.

Menhaden support predators throughout the Atlantic coastal ecosystem, including striped bass, bluefish, weakfish, marine mammals and seabirds. ASMFC's own ecological reference-point framework recognizes this role. Yet the 2025 assessment found fishing mortality above the ecological target, and ASMFC determined that a reduction of 50% or more from the previous TAC would be necessary to substantially reduce the probability of exceeding that target.

Equally important, the current assessment evaluates menhaden primarily at a coastwide scale. ASMFC acknowledges that existing models cannot determine stock status at smaller spatial scales. A coastwide determination that menhaden are not overfished therefore should not be treated as proof that intensive, concentrated harvest cannot reduce forage availability within individual bays, nearshore waters or migration corridors.

That uncertainty argues for precaution, particularly where industrial-scale harvest overlaps concentrated schools of forage fish, predators and migrating wildlife.

I support substantially reducing commercial menhaden harvest and establishing the following coastwide protections:

1. Substantially reduce the coastwide TAC. At minimum, management should seriously consider the 50%+ reduction identified by the 2025 assessment as necessary to reduce the risk of exceeding the ecological fishing-mortality target.
2. Establish vessel-level daily, weekly and seasonal limits. A coastwide annual quota alone does not prevent intense removals from one place over a short period. Limits should prevent individual vessels or fleets from removing an ecologically significant concentration of forage.
3. Establish seasonal closures during major migrations. I support prohibiting directed commercial menhaden harvest from April 1–June 15 and September 1–November 30 in coastal migration corridors. The precise dates should be refined using regional migration and ecosystem data.
4. Create a minimum seven-mile coastal and bay buffer. Large-scale commercial harvest should be moved away from beaches, inlets, estuaries and other areas where predators and forage become concentrated. The appropriate distance should be evaluated scientifically, but meaningful spatial protection is needed.
5. Limit participation and industrial fishing capacity. Management should evaluate limits on permits, vessel capacity and consolidation of harvest privileges so that increased efficiency cannot continually increase localized fishing pressure.
6. Strengthen bycatch requirements. Harvesters should be responsible for minimizing bycatch through improved gear and fishing practices, with meaningful penalties for preventable or excessive bycatch.
7. Require comprehensive monitoring. Landings, locations, bycatch and fishing effort should be independently verifiable. Electronic monitoring, vessel tracking and dockside verification should be considered for high-volume operations.
8. Make violations economically irrational. Illegal or excess harvest should be confiscated and substantial quota violations should carry escalating fines, permit suspension and, for serious or repeated violations, license revocation.
9. Create a per-pound conservation and enforcement assessment. Commercial menhaden harvest should contribute directly to the cost of monitoring, fisheries enforcement, ecosystem research and improved spatial stock assessment.
10. Prohibit spotter aircraft and evaluate restrictions on high-capacity harvesting technology. Management should consider whether technologies that enable extremely rapid removal of concentrated schools are compatible with ecosystem-based forage-fish management.
11. Prioritize essential uses of a limited forage resource. Regulators should examine the end uses of reduction-fishery products and whether demand for fish meal, fish oil, supplements and aquaculture inputs can be reduced through viable alternatives. Menhaden's ecological value should be considered alongside its commodity value.
12. Establish measurable ecosystem triggers for further action. If forage availability, recruitment, predator condition or other scientifically defined indicators deteriorate, management should automatically trigger additional reductions, spatial closures or a temporary moratorium rather than waiting for the next prolonged regulatory process.

Atlantic herring demonstrates why precaution matters. The 2026 assessment estimates Atlantic herring spawning-stock biomass at approximately 35,528 metric tons compared with a target of 188,214 metric tons—only about 19% of the target—and the stock remains classified as overfished.

We should not wait for menhaden to reach a comparable condition before taking aggressive action.

The central issue is not simply whether the coastwide menhaden stock has crossed an overfished threshold. The question is how much forage should remain in the ocean, where it should remain, and whether concentrated industrial removals are compatible with a healthy coastal food web.

When scientific models cannot yet quantify localized depletion, that uncertainty should not be interpreted as evidence that localized depletion does not occur. It should justify precaution.

Menhaden are worth more to the Atlantic ecosystem than their landed value alone. Management should reflect that reality by substantially reducing harvest, protecting nearshore forage concentrations, limiting concentrated removals, and placing the burden of monitoring and compliance on those commercially benefiting from the resource.

This addendum is desperately needed. We have seen what overfishing does first hand in regards to ecosystem breakdown (i.e. food chains become dismantled leading to die offs of marine birds and other aquatic species) I understand that the fisheries need to fish to survive and be able to pay the bills. However, we know that protecting the future of the entire ecosystem works when we cap fishing amounts of certain species and couple it with restoration efforts of the waterway. This addendum will protect all of us for the future.

Please take action to stop the overfishing of Menhaden in the Chesapeake Bay. Chesapeake Osprey chicks are starving by the thousands from the decline in Menhaden, portending a substantial 14% annual decline in the Osprey population. More than 30% of adult female Ospreys are failing to breed. This tragedy is linked to the massive harvest of Menhaden allowed by Virginia to feed the Omega Protein fish meal production pipeline in Reedville, VA.

The Omega Protein argument that reducing the Menhaden harvest will ruin jobs is grossly incorrect. By overfishing, there will unlikely be enough fish for Omega Protein to continue processing, thus eliminating jobs entirely. And ospreys are not the only concern. As menhaden disappear so do blue crab populations and sport fish such as rock fish, weakfish, bluefish and spiny dogfish. The loss of key commercial marine life will negatively impact residents and the many businesses that support tourism and outdoor adventures.

These combined disasters would be a significant economic loss to the entire Chesapeake Bay region, the state of Maryland, and points beyond. The need for urgent action is now. Thank you for your attention.

As a USCG Captain operating a fishing charter business both inside the Chesapeake Bay and the Atlantic Ocean, I am strongly in support of Addendum II and hope that there will be strong consideration to maximize the "up to" 50% reduction and help protect the Atlantic Coast. While many issues affect population and migration in the Mid-Atlantic area, none is as impactful as the Menhaden reduction fishery. Please protect our bunker and wildlife that depend on them before it's too late.

As a concerned citizen of the Chesapeake Bay fishery and a sportsman, i urge the committee to vote the following:

3.1 Chesapeake Bay Reduction Fishery Cap Amount

Option C1e: To reduce the Chesapeake Bay CAP by at least 50 percent in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).

3.2 Chesapeake Bay Cap Distribution

Option B2: To establish three even length quota periods for the Chesapeake Bay Cap, distributing the harvest at 25% in period 1, 25% in period 2, and 50% in period 3.

Section 3.2.2 – Chesapeake Bay Cap Distribution – Quota Period Overages & Underages

Option B: Provides any underage of Quota Periods 1 or 2 be rolled into Period 3 of the same fishing year. Any underage in

Quota Period 3 would not be reallocated. Any overages would be deducted from the same quota period in the following year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision

Option B: Revisit the Chesapeake Bay Cap every 3 years.

A sustainable harvest should include Menhaden hatchery and farms in any Addendum. Not simply vacuuming natural Menhaden from the Ocean and Bay. There are other strains on the fish such as habitat loss and pollution which need to be considered as well. Thank you for your attention to this matter.

Here in New Jersey, from my personal Observations , I have seen a large drop off of every year class menhaden In our rivers bay's coastal and Offshore waters.
This is evidenced by the lack of whales and other marine mammals , right along the shoreline , who are custom to feeding on these menhaden from the spring Through late fall.
I support all Actions to protect and reduce the commercial pressure on the stock.

Subject: Public Comment on Atlantic Menhaden Draft Addendum II – Chesapeake Bay Cap and Allocation
To: Atlantic States Marine Fisheries Commission (ASMFC)
From: John Powers, Tidewater Anglers Club Recreational Angler, Virginia Resident, VSSA Member
Dear Members of the Atlantic Menhaden Management Board,
I am writing to submit formal comments on Draft Addendum II to Amendment 3 of the Atlantic Menhaden Fishery Management Plan. As an angler and advocate dedicated to the long-term ecological health and economic vitality of the Chesapeake Bay, I urge the Board to adopt the most robust, precautionary conservation measures available under this draft.
Atlantic menhaden serve as the critical keystone species of the Chesapeake Bay, underpinning the forage base for striped bass, bluefish, osprey, and countless other species. Because the Bay functions as the primary nursery ground for both menhaden and key predator populations, localized depletion from concentrated industrial purse-seine fishing severely threatens the entire estuarine ecosystem.
To safeguard this critical resource and enforce strict accountability, I strongly support the following options:
Section 3.1: Chesapeake Bay Reduction Fishery Cap Amount
• Support Option C1e: Reduce the Chesapeake Bay CAP by at least 50% in 2027 and link any changes to the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).

o Rationale: A 50% reduction is an essential, long-overdue step toward preventing localized depletion. Concentrating industrial reduction harvest in the restricted, shallow waters of the Bay deprives predators of sufficient biomass during crucial feeding periods. Furthermore, pegging the Bay Cap to a maximum of 13.6% of the coastwide TAC ensures that Chesapeake waters are not disproportionately burdened by future shifts in coastwide quotas.
• Support Option C2a: Set the maximum upper limit in any future change at the current level of 51,000 mt.
o Rationale: Establishing a strict ceiling at 51,000 metric tons guarantees that, regardless of future coastwide stock assessments or TAC increases, industrial harvest within the vulnerable Chesapeake Bay cannot expand beyond historic baselines. This provides an absolute safeguard for nursery habitats.
Section 3.2: Chesapeake Bay Cap Distribution and In-Season Management
• Support Option B2: Establish three even-length quota periods distributing harvest at 25% in Period 1, 25% in Period 2, and 50% in Period 3.
o Rationale: Dividing the quota prevents the industrial fleet from sweeping through schooling menhaden in a short window during early-season nursery and predator feeding windows. Spreading harvest pressure limits immediate localized shortages, giving juvenile fish and resident predators the forage buffer they need during peak spring and summer months.
• Support Option B (Accountability & Rollover): Allow underages from Periods 1 or 2 to roll into Period 3 of the same fishing year; do not reallocate Period 3 underages; deduct any overages from the same period in the following year.
o Rationale: This structure enforces real accountability. A 100% pound-for-pound payback for overages creates a meaningful deterrent against exceeding limits. Concurrently, retiring unharvested quota at the end of Period 3 ensures that unused fish remain in the water to fulfill their ecological role rather than artificially inflating subsequent harvest caps.
Section 3.3: Chesapeake Bay Reduction Fishery Cap Revisit Provision
• Support Option B: Revisit the Chesapeake Bay Cap every 3 years.
o Rationale: Given ongoing fluctuations in climate, water quality, and predator health (particularly the struggling Atlantic striped bass stock), management decisions cannot be left static. A mandatory three-year review cycle guarantees that ASMFC regularly integrates the latest Ecological Reference Point (ERP) data, local diet studies, and juvenile abundance indices into the Bay's harvest limits.
Conclusion
The Chesapeake Bay cannot afford business-as-usual management for industrial reduction harvest. The ASMFC has made significant strides in embracing ecosystem-based management, and adopting Option C1e, Option C2a, Option B2 (with Option B accounting), and Option B under 3.3 will put those principles into practice where they matter most.
Thank you for your dedication to our marine resources and for giving strong consideration to these vital conservation measures.
Sincerely,
John Powers

Comment

To whom it may concern:

I would never have envisioned myself taking the time to make a public comment about caps on fishing if it were not for the story of finding a starving osprey on our Stockton University campus (Galloway, NJ). Ospreys, as it would have it, are our school mascot, and I have been following the work of one of my colleagues, Melanie Schroer, who has been exploring the possible causes of the depletion of the osprey population across the Eastern seaboard.

What seems to have become clear is that ospreys are starving - they are starving because the supply of feed fish is diminishing. To see pictures of emaciated ospreys and the chicks they were unable to raise is horrible, and unlike many of the issues we face in our world today, this is one we have the potential to change. I strongly oppose lifting the caps on the fishing of Menhaden. I am old enough to remember the days when the threat of losing the Bald Eagle and Condor was real - we have seen those populations surge again, but we should not choose this (and, yes, it would be a choice) for ospreys.

Please, we cannot let our legacy of environmental stewardship be the bodies of emaciated birds of prey for our children to look at and wonder what their parents might have done.

Comment

My name is Jen Cookus, and I am a concerned citizen from Baltimore, Maryland. I am deeply concerned about declines in osprey populations and the potential impacts of menhaden depletion on the health of our coastal ecosystems.

I support precautionary, science-based menhaden management that recognizes their essential role as a forage species and the importance of maintaining sufficient populations to support the birds, fish, and other wildlife that depend on them.

Osprey populations can serve as an important indicator of ecosystem health. Their success is closely tied to the availability of healthy fish populations and functioning aquatic ecosystems. I believe the concerns raised by Dr. Brian Watts and other scientists studying osprey and menhaden along the Atlantic coast warrant serious consideration in management decisions.

I urge the Commission to take a precautionary approach that prioritizes the long-term health of menhaden populations and the broader ecosystem over short-term harvest levels. Management decisions should be informed by the best available science, including research on predator-prey relationships, and should account for uncertainty and potential ecological consequences.

Protecting menhaden is not just about sustaining one fish species; it is about supporting the interconnected health of the Chesapeake Bay and our coastal ecosystems for future generations.

The value of the bay to the community, watershed, mid-Atlantic, and the nation cannot be overstated. It's iconic for its history, natural beauty, and as an economic powerhouse. A cap on harvesting menhaden, the life blood of the bay, is a fair and reasonable approach to ensuring that the bay is healthy and productive for decades to come.

As a resident of Maryland, one who lives on the water, and admirer of the Osprey, I am witnessing firsthand the reduction in productivity as a result of overfishing the menhaden. Although there are likely many other contributors to reduced food for the osprey, there is no greater direct correlation than the reduction of their immediate and favorite food source!

Elected Officials - Please Act NOW to put safeguards, quotas and caps on overfishing the menhaden to protect our bay!!!

I am a resident of Chesterfield County, VA. Although I cannot claim to be a fisheries expert, I think I have common sense. The impact on osprey populations is a concern. The impact on striped bass is another concern.
The problem as I see it is that Omega Proteins has a technology edge over Menhaden. Omega proteins has spotter planes and vast nets. Menhaden only has one weapon, the ability to reproduce. So far, it does not appear that Menhaden is keeping up in this competition.

Menhaden is not in danger of extinction. The danger is that it simply is not able to serve as the keystone species for other fisheries and ospreys, while also feeding the enormous demand from a heavily leveraged industry that has to pretend that there is plenty for all the consumers of menhaden.
There isn't plenty to go around. It is a similar situation to the Colorado River water lifeline to the Southwest USA. The difference is the glaring situation with the Colorado River is now resulting in hard choices being made, while the Menhaden mess is just resulting in more pretending.

It's been incredible to witness the resurgence of the ospreys along the Jersey shore. My grandparents bought a house in Barnegat Light in 1978 and I've been fortunate enough to spend every summer of my life there. I even recently got into fishing in the bay by the lighthouse.

The past couple of years have been disheartening. It's been hard watching the ospreys fly out to sea and back over and over throughout the day without a single catch. Myself and other fisherman wait and wait for a nibble and come up with nothing. The decimation of menhaden, a keystone species, is a dire warning that our actions, not only commercial fishing but also carbon emissions, are exhausting the ecosystem faster than it can repair itself.

Drastic regional action is imperative. A 50% reduction in the fishery cap does not go far enough. Funding to better understand the impact of climate change on the menhaden population and possible solutions is also required, along with a task force for rapid implementation. These converging crises are not waiting around for us to act.

As a recreational saltwater angler, I see firsthand the importance of a healthy menhaden population to the overall health of our fisheries. I believe menhaden management must prioritize the health of the marine ecosystem and ensure that sufficient forage remains available for predator species.

I strongly supports taking additional steps to protect and rebuild Atlantic menhaden populations. Menhaden are one of the most important forage fish in our coastal waters and are a critical food source for striped bass, bluefish, weakfish, tuna, Osprey and many other species

I urge the Atlantic States Marine Fisheries Commission to adopt responsible management measures that reduce fishing pressure on menhaden and protect this vital resource for future generations of recreational fishermen.

I have no ospreys left. I have even built them a nest on a piling and platform in the cove that I had built just for ospreys. No takers for the third year in a row.

We no longer see the schools of baitfish that used to be abundant in our river. (Tred Avon River). It is no wonder there are fewer ospreys.

Send that Canadian (Omega) company who works in the Chesapeake Bay back to Canada with a note to Prime Minister Carney that says “Return to Sender”.

Comment

Dear Commissioners,

The Friends of Indian River is a local community group striving to improve the quality of life for all the residents of the community in Chesapeake, Virginia, by promoting and preserving a healthy and clean river, shorelines, parks, and green spaces. Our local waterway is a tributary of the Elizabeth River on the Chesapeake Bay. As has often been said, menhaden may be the most important fish in the sea at the base of the aquatic food chain. Striped bass, osprey, red drum, marine mammals, and many other species depend on menhaden. Recreational fishing is important in our community. We are just now seeing the return of otters to the Indian River. Ospreys are an iconic bird in our skies. But all of these are threatened by the shrinking of the menhaden fish population. The failure of osprey nests is perhaps one of the most easily observed issues.

We urge the Atlantic States Marine Fisheries Commission to take action to better protect menhaden and support a healthy Chesapeake Bay ecosystem, including by reducing the Bay Cap by 50 percent in 2027 and implementing quota periods to more effectively distribute reduction fishing pressure throughout the season. Specifically, we support the following options in Draft Addendum II:

3.1 Chesapeake Bay Reduction Fishery Cap Amount: Support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.

3.2 Chesapeake Bay Cap Distribution: Support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. Also, support option B which establishes quota period overage payback and rollover of unused quota within a fishing year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

Urgent action is needed. We respectfully ask that you implement the above listed options at your next meeting.

Sincerely,
Rogard Ross
President, Friends of Indian River

Dear Members of the Council:

I am writing to urge you to fully adopted reductions in menhaden harvest and to ensure that annual harvest remains below 115,000 metric tons. If management and scientific considerations allow, I also encourage the Council to pursue a harvest level of 100,000 metric tons or less.

Menhaden are an important forage fish and provide a critical food source for striped bass and numerous other marine species. Keeping harvest within a conservative limit is important to maintaining a healthy and resilient coastal ecosystem.

I respectfully ask the Council to:

Enforce a maximum annual menhaden harvest of less than 115,000 metric tons.
Consider 100,000 metric tons or less as a more conservative management target where supported by the available science.
Maintain rigorous monitoring and reporting of menhaden landings throughout the fishing season.
Take timely enforcement action when harvest approaches or exceeds applicable limits.

Make harvest, monitoring, and compliance information publicly available.
Continue evaluating scientific data and fishery conditions to determine whether further reductions are appropriate.

Adopting a reduction is only the first step. Consistent enforcement and transparent monitoring are essential to ensuring that management measures achieve their intended conservation objectives.

Thank you for your consideration and for your work to protect the long-term health and sustainability of our coastal fisheries.

Sincerely,

william suplee

Comment

My name is Matthew Yoder and I am a Virginia resident concerned about Chesapeake Bay menhaden as well as the species and communities dependent on a healthy menhaden population.

Osprey are these beautiful birds that soar and dive for exactly the fish that is currently being decimated. They are dying. Unable to feed their chicks, their families collapsing. 4 out of 5 nests failed this year. Speaking with other bird watchers, I've learned that the numbers don't lie, there are far fewer of this magnificent creature in Virginia that in the past as their food source is hoarded away.

The birds are not the only ones who suffer. The dolphin and whale populations, as well as game fish, heavily rely on these bait fish. That means that to feed the fish oil industry, we are killing our own game fishing industry, whale/dolphin watching industry, and a magnificent part of our bird watching industry/tourism.

This unchecked menhaden fishing has got to be reined in. I support Addendum II to Amendment 3 of the Atlantic Menhaden Interstate Fisherery Management Plan.

The Atlantic Menhaden fishery is overfished. The most important fish of the sea is critical for every predator in the epipelagic zone. Not only are they important prey, the schools are very effective for their ability to filter feed.
They are the largest filter feeders and clean the water better than oysters, because of the mass, and ability to swim.

I own a property in Middlesex County, Virginia, on the Rappahannock River. My road (Montague Road) has frontage on the river of about 3/4 mile. In that span of frontage, there are around 10 platforms on pilings for Osprey. When I bought the property in 2015, there would only be one or two empty platforms. This summer, there is only one nesting pair of Ospreys along this span. I no longer see schools of peanut bunker off my dock like I used to. Something is not right.

I have monitored three Osprey nests for the Connecticut organization Osprey Nation for the past 5 years. My nests are located on the shore of the Long Island Sound in the town of Guilford, CT. My nests were successful every year, each producing 1-2 offspring. This year, the adult ospreys arrived at the nest platforms, but all 3 nests were abandoned after a few days. All of my friends who monitor nests in this part of Long Island Sound had similar experiences. We have since heard that it is because the Menhaden population in the Sound is markedly reduced due to over-fishing them for fertilizer production. The lack of Menhaden in the Sound meant the larger fish had nothing to feed on, thus drastically reducing the number of fish in the Sound. Osprey only eat fish, so their only source of food was gone, and they did not stay in the area and did not reproduce this year. We hope this situation can be remedied.

Limiting menhaden harvesting is vital to the survival of sea life, mammals and osprey. Here in NJ we lost multiple baby osprey this year due to starvation. Allowing for commercial fishing to deplete these natural resources will destroy ecosystems. Aren't humans doing enough to destroy everything valuable on this planet already or will we only be happy with total obliteration.

Thank you for the opportunity to comment. I support a reduction in the cap on menhaden fishery quantities allowed in the Chesapeake Bay. I also support a later distribution of those allowable limits during the seasons to protect against the early achievement of the maximum allowed limit. Finally, I support the more fair distribution of fishery allowed amounts up and down the entire Atlantic seaboard so such an abundant percentage does not come from the Chesapeake Bay itself. I would like to see a reset of the balance of commerce and nature that has unfortunately been lost in favor of the fisheries and away from wildlife in the Chesapeake ecosystem.

I support the 50% reduction in the Chesapeake Bay TAC, this should not be linked to the total coastwide TAC. I also support a 30% or more reduction in the total coastwide TAC. I live in Ocean City, Md. Schools of bait fish are nowhere to be found. Juvenile fish can no longer be found in my canal and in the backwaters of the Coastal Bays. The ASMFC needs to take drastic action NOW. Do your job and stop protecting special interests that only represent a very tiny population of the citizenry. Kicking the can down the road will have dire ramifications for multiple species. Furthermore, unused quote should not be reallocated to other States. You will just create a crisis in a different ecosystem, like is happening in the Chesapeake. It is clear to me that there are not as many Menhaden in our bays and oceans as was once previously thought. Thank you. ~Michael Lloyd, OCMD.

Omega somehow feels that the menhaden in the oceocean are their fish. These forage fish are there for use by first the species that use them for their sustenance. Then next for the commercial and recreational fishermen of the United States. This Canadian company is taking forage fish from our costal waters to the detriment of the fish and wildlife who depend on them. Ecologically they are an important filter feeder to cleanse the ocean. Omegas harvesting practices are barbaric Allowed unchecked they would be happy to net every last bunker. The products that Omega is selling with the reduction are available by other means. I question if they are even sold in the USA. Our fish for their profit to other countries. My opinion is their operation should be removed entirely from the east coast

I live on a creek that drains into the Chesapeake Bay, and for two years now, the ospreys in the nest next to my dock have not produced successful offspring. I'm growing increasingly concerned that the declining menhaden population is the limiting factor. It is critical that sustainable fishing limits be established and implemented ASAP to save the declining osprey population and for the overall health and economic viability of the Chesapeake Bay food web.

Stop the overharvesting of Atlantic menhaden in the Mid-Atlantic region and Chesapeake Bay. This is highly destructive to fisheries and has resulted in some of the worst fishing in many years. Plus all manner of wildlife, including osprey and eagles look to menhaden to sustain life. Protect our environment and wildlife for the next generation, don't destroy it for corporate greed.

Headlines such as this one "2026 osprey breeding performance was the worst ever recorded for the Chesapeake Bay" published by the Center for Conservation Biology at William and Mary are alarming. Many factors contribute to the variability in osprey breeding success, but this year they noted that food stress was notable. The food stress appears to be tied to the decline in the availability of menhaden. Why are the menhaden unavailable to the osprey at the time that they are breeding (April, May, and June)? This is a key question to answer and if the menhaden decline is caused by commercial harvests, then I believe those harvests should be regulated with a fisheries cap.

Read the history of menhaden harvesting from New England and the history of menhaden harvesting in Virginia, North Carolina and Louisiana. Once you've educated yourself on this subject, you'll understand that this fishery will not be sustainable without taking proactive steps now. Nor, will the many other species of fish and fowl be able to thrive without an abundance of menhaden. I urge everyone to contact their representatives at all levels and encourage them to do the right thing and protect OUR resources, before there's nothing left to protect. Let's stop fighting this battle on social media and start fighting it in the voting booths.

I am writing to convey the need for stronger protections for the future of osprey on the coast. Based on present 2026 monitoring, osprey nest success in Rehoboth, Assawoman Bay and Lewes is below the minimum levels for osprey populations to thrive due to starving chicks and the depletion of a their main food source—Atlantic menhaden. This is due to over harvesting and no or minimal guidelines and laws that will lead to the inevitable extinction of osprey on our coast if left to continue unchecked. It is critical that we enact fishing policies now to allow enough food for osprey survival. The best time to do this was yesterday, and the next best time is NOW. Please help protect our beautiful and beloved raptors and wildlife on our coasts. Thank you!

Thank you for the opportunity to comment on the Draft Addendum II to Amendment 3 to the Interstate Fishery Management Plan for Atlantic Menhaden. Below are my recommended actions based on the alternatives (Section 3) in the document for public comment. For clarity I follow the section numbers and alternatives as they are described.

3.1 Chesapeake Bay Reduction Fishery Cap Amount, Option B, sub-option B4.

This option yields a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt. This option is an important precautionary measure to rapidly address multiple issues of availability of menhaden in Chesapeake Bay for reproduction as well as functional ecosystem needs such as prey for multiple predators.

3.2 Chesapeake Bay Cap Distribution.

3.2.1. Quota Period, recommend Option B1.

This even length and even harvest strategy results in three quota periods that allow 33%, 33%, and 34% exploitation of the

total Bay Cap. While option B2 slightly reduces exploitation during the earlier part of the fishery, it would allow a larger disturbance to menhaden numbers and distribution during the third quota period. Given the functional role that menhaden play as prey for multiple predators within the Chesapeake ecosystem, spreading the effect of the fishery evenly throughout the annual fishing cycle minimizes prey depletion effects across predator species, predator size classes, and distribution of menhaden aggregations (all where predator-prey interactions and resultant energetic benefits can be both dependent on prey size and distribution).

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages. Recommend Option B (I think).

I recommend this alternative should yield no payback for overall underage between fishing years but allow rollover of unused quota within a fishing year. An underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3 rather than be added only to Period 3. This would avoid the ecological effects described in my recommendation for quota period.

The detailed descriptions of these alternatives in the addendum were hard to follow so my previous statement hopefully adds clarity to my intent.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision, Recommend Option B.

To assess the response in menhaden populations to management actions, I recommend the Chesapeake Bay Cap be reviewed every three years, unless there is such a rapid reduction in the Bay population (fishery or non-fishery related) that a management response is necessary.

Coastwide TAC

To address an earlier error in the assessment process that predicted a larger menhaden population than a subsequent analysis produced, the 2025 Coastwide TAC was cut by 20%. Unfortunately, the calculation for the 2025 TAC was equal to the actual 2024 catch. It appears that the reduced TAC produced no real conservation benefit. A 50% reduction, to 94,420 MT (conserving the potential for overage), should be implemented to address recovery and sustaining the ecological role this species plays along the coast.

Thank you, in advance, for your consideration.

Sincerely,
Peter J. Auster, PhD

I moved to the eastern shore in 2003 for the beauty of the ecosystem. That has drastically changed for the worse since then with the loss of habitat, killing of insects and other food sources for larger animals and the number of birds have suffered drastically. I am begging you to please do the right thing here and place a hold on ALL menhaden fishing in the Chesapeake Bay Watershed immediately until numbers can have the chance to improve. We do not have time to waste here. I am personally witnessing the death of so many osprey chicks. It is utterly heartbreaking and completely unnecessary. We don't have time for two or more years of surveys when everyone knows exactly what the problem is. If I were not scheduled to be out of country, I would be there in person to fight the fight. We are destroying this world faster than I could have ever imagined possible and we are losing everything that is beautiful about it. The amount of suffering we caused to the natural world and the animals in it is preventable. We must do better!
Let's start here.

The 50% reduction in menhaden fishing allowed is a critical first step to recovering what we have lost in the bay. Omega says there is no evidence it is their reduction fishing, but anyone with two eyes and half a brain can see the causation. They come through with their ships catching millions of tons of menhaden, and in their wake, fish and osprey starve. The fishing has plummeted in recent years. Lifelong fishing guides have had to close their businesses, and my children have not enjoyed what I have enjoyed my entire life: fishing successfully on the bay. Reduction fishing for menhaden should be banned, but this is a step in the right direction.

Omega"s gross overfishing of menhaden in the Chesapeake is an obvious horror story.The birds no longer catch them in my Norfolk creek.I have not seen an osprey on the Lafayette this year.I can not believe that our legislators are so craven and corrupted by Omega money.

Menhaden are one of the most important fish on the AtlanticCoast. They are vital not just as a food source to the birds and fish that callthe coast home, but also as a key forage fish species that many of our baitfisheries, coastal communities, and small businesses rely on. The Ospreypopulation has struggled in recent years, and it has become clear that ahealthy menhaden population is critical to the health of the entire ChesapeakeBay ecosystem.

As a concerned stakeholder, I want to thank you for theopportunity to comment on Draft Addendum II. I support the following managementoptions:

3.1: Options C1e and C2a. I support a precautionaryreduction in the Bay Cap by 50% of the current 51,000 metric tons for thereduction fishery. This will help increase the number of menhaden available inthe Chesapeake Bay, an important nursery for Atlantic menhaden.

3.2: Option B2. I support the establishment of three quotaperiods for the Bay Cap at a 25/25/50% harvest distribution percentage perquota period. This will help reduce food competition for birds like ospreyduring the most vulnerable times of their life cycles.

3.3: Option B. I support reviewing the Chesapeake Bay Capevery 3 years. This gives the Commission the ability to plan and react tochanging conditions and new information.

These options best support the Chesapeake Bay and ensure thehealth of our birds, people, and planet.

Sincerely,
James M Donahue

Menhaden are critical food source for many species, especially Osprey. This year, due to depletion of menhaden by over-fishing, Osprey population collapsed. Very few chicks fledged and adults starved.
Since the ban on pesticide DDT in the 1970s, Osprey and Bald Eagle populations recovered spectacularly. Now those populations are being starved. We cannot allow this to continue.

It is IMPERATIVE that the Menhaden fishery be protected to the MAXIMUM amount in order to protect the bay from ecosystem collapse! When top tier predators like Osprey are dying of starvation you have a BIG problem. There needs to be a menhaden catch moratorium until populations can rebound.

We need a moratorium on commercial harvesting of Menhaden for a minimum of five years, preferably longer. This will allow the recovery of menhaden that are a vital part of the food chain in the North Atlantic. We are seeing indications that over harvesting of menhaden is causing declines in striped bass and other marine and terrestrial species.

Growing up in Ocean View in Norfolk, Va, I had never seen a bald eagle or an osprey in the wild. Years later as the Chesapeake Bay became healthier, we would see them! Such a thrill!
However, now they are threatened by starvation due to overfishing by commercial companies. Please consider enacting a policy to reduce what can be harvested so there's enough to provide food for these magnificent birds and other creatures that depend on menhaden to survive.
Thank you.

Comment

I would like to ask the ASMFC members to consider a regional management program be used in the quota selection for the states that harvest menhaden. Maine and other states in New England have lost fishing opportunities this year because of the displeasure of Omega Industries huge quota, and fishing practices in the Chesapeake Bay Area. The Maine Lobster Industry depends highly on using the biomass in Maine waters to provide and local and affordable bait supply to the lobstermen of Maine. This fishery also takes fishing pressure off the obstetrician resources, as it allows people to diver their fishing operations into another resource, which is important for the small coastal towns that have only one fishery to utilize.Maine has lost an entire month of harvest opportunity this year with the 20% reduction in quota this year, even with transfers from other states.Maine has its conservation measures in place for small scale harvest operations, and the event that overfishing would occur is minimal with the boat size and weekly harvest limits. We could manage things better at a state level, but the state quota needs to be stable in order for that to happen. It was stated in the meeting last fall at ASMFC that there was no available science on the menhaden biomass above Rhode Island. This is why I believe regional management of resource that is spread out such a great distance needs to be implemented.Thank You ,Doug McLennan Spruce Head Maine

I am overwhelmingly in support of easing the pressure on menhaden populations caused by industrial harvesting. My family enjoys the waterways of the Chesapeake Bay and understand the critical issues of overfishing.

Public service in a coastal city means paying close attention to critical issues like this, even when they aren't decided at City Council. We absolutely need leadership that understands what's happening in our waters and listens to the people who depend on it.

Please vote to protect our marine ecosystems healthy and preserve our natural heritage. Osprey are by far my favorite raptor species and have spent countless hours and days watching them. To hear they're now facing a decline after decades of healthy populations is absolutely heartbreaking. We need to remember that we are a part of the ecosystem and the natural cycles of this planet and wholeheartedly embrace a change of mindset to protect the living things that cannot stop the destruction of industry. Please protect the bay!!!

Good people try. Noble people attempt to abrupt harm. We all are watching catastrophic flooding in our country the past 5-8 years on a regular basis now. It's not once every 10-15 years in a state we mulled over that it couldn't be prevented because that's how bad luck works. Clearing the tree canopy, bulldozing small & large wooded tracts, paving over small strips of vegetation & removing the topsoil on development sites has all contributed to local flooding and the collective shift in wind & water currents that stall & endanger life in chaotic arrival. Deposition or rain & speed of ground strike along with the extensive removal of natural strips of land with varying overlooked topography as valuable, has been man made by development continuing past need or public wish. Our counties & cities are creating peril to lives & home & cars with risk in travel & stress in maintaining jobs that pay ever increasing tax assessment that enriches county coffers & whims, but continues to strain mental & physical adaptability for residents & citizens countrywide. I worked with a developer for several years & he said he could get men to open their wallet & buy just by inflating ego with "It's all about you". What is happening to our wildlife as all this distraction is occurring? Our whales are beaching showing starvation. High tech fishing trawlers are using their new technology to locate & net entire schools of small feeder fish to grind up & use as cheap fertilizer. Then they vacuum the fish from the nets & move to the next school already mapped out & soon located. Vacuum that school & go to the next. The whales are starving to death because they require a huge volume of tiny fish in order to make it to their migration site or to a breeding ground where just one baby will be born months later. They can't reach their destination for migration or safe nursery

as dozens beach showing "they are like a hollow bag of bones. No fat. No insulation or energy available". People did this by their government's allowance & people can stop it. Birds are arriving to their migration routes seasonally & no food is present. We have changed the season of provisions by massive pollution & aerial spraying too. Caterpillars used to provide but are not present as birds race through storm & winds & miles to go. Hawaii allows the tilling of plastics into the soil from Dole? A paradise of poisons in the drinking water & high rates of cancers in ... paradise? What about birds that rely on food from bays & oceans? Raiding everything that isn't even humanly edible, osprey are starving too. We are killing all life on the planet by overt actions of clearing & development & toxic pollution or poisons. Starving whales & osprey? That has the same cause. No food to sustain. Unimaginable? It once was 15 years ago. You choose. Don't let anyone take the right to choose for you.

Thank you ...

Draft Addendum II, which will consider reducing the Chesapeake Bay reduction fishery cap by up to 50%, does not go far enough. The Chesapeake Bay fishery cap needs to be reduced by at least 80%. The present uses of menhaden benefit nobody except those who profit by catching and processing the fish and selling the finished product. None of the uses are actually necessary. In contrast, the fishery's adverse environmental impacts, which likely include declines in populations of other fish species, ospreys, bald eagles, and other parts of the food chain, are immense.

As a concerned citizen who cares about the health of the Chesapeake Bay ecosystem, I strongly support a 50% reduction in the Chesapeake Bay reduction fishery cap. There is declining productivity and widespread nest failures among ospreys, which signals an urgent need for precautionary conservation. Your immediate attention to this matter is greatly appreciated.

I support a 50% reduction in the
menhaden catch. Although the there is not certainty that overfishing of menhaden is causing the abysmal reproduction rate of osprey, the evidence strongly suggests that this is so. Menhaden ate a keystone species in our coastal waters, and their depleted numbers are hurting more than osprey.

Thank you,
Jean Hollings

I support the establishment of three quota periods for the Bay Cap at a 25/25/50% harvest distribution percentage per quota period. This will help reduce food competition for birds like osprey during the most vulnerable times of their life cycles.

I strongly feel that our public institutions must support a balance of needs for humans, wildlife, and the planet in general. We're seriously impacting our natural environment and any time policy decisions can help maintain human needs and those of the natural environment we need to be very careful.

Hello, the 50% reduction of harvesting of menhaden is not enough. You must go for a 100% reduction of current harvest allowance. The current harvest amounts have already done the damage; it is a multi-year accumulation of damage. To stabilize further environmental deterioration, you must stop the bleeding.

If you were driving down the road and saw that you are about to hit a wall, would you step on the brakes at 50% or 100%?

I monitor osprey nests along a small part of the Indian River Bay, and there are either no parents or no fledglings that can fledge because they become too emaciated to fly and catch fish.
I would like a 50%/13%/25%/60 split every 3 years to see and/or prove that it is indeed the overfishing of menhaden. There is only one way to know: enact the Menhaden Addendum.

Please vote to protect our marine ecosystems healthy and preserve our natural heritage. Osprey are by far my favorite raptor species and have spent countless hours and days watching them. To hear they're now facing a decline after decades of healthy populations is absolutely heartbreaking. We need to remember that we are a part of the ecosystem and the natural cycles of this planet and wholeheartedly embrace a change of mindset to protect the living things that cannot stop the destruction of industry. Please protect the bay!!!

I am writing as a former Naval officer, a waterfront landowner along the Chesapeake Bay for over twenty years, and an avid boat operator to urge the Board to approve Option B4 (a 50% reduction in the Chesapeake Bay reduction cap to 25,500 metric tons) and establish seasonal quota distributions under Draft Addendum II.

Navigating these waters for more than two decades, both professionally and as a private mariner, I have developed an acute operational awareness of the Bay's surface conditions and marine life. In years past, running the tributaries and open reaches meant regularly encountering dense, surface-breaking schools of Atlantic menhaden. Today, those once-prevalent bait schools are conspicuously absent from our sounders and wakes.

The consequence of this absence is an undeniable ecological crisis. Atlantic menhaden serve as the primary caloric engine of the Chesapeake Bay's food web. Without this critical, lipid-dense forage base, our top predators are starving—most visibly our resident osprey population. From the water and my shoreline, I have watched returning pairs search empty shallows for hours, only to return to nests where chicks steadily perish from malnutrition. Coastwide single-species models declaring menhaden "not overfished" completely obscure the destructive reality of localized depletion caused by industrial purse-seine reduction operations in nearshore nursery waters. Industrial fleets scooping up entire schools to manufacture aquaculture pellets, animal

feed, and oils are systematically stripping the estuary of its life support.

To restore balance to these vital waters, I ask the Board to enact:

Bay-Specific Ecological Reference Points (ERPs): Quotas must account for the multi-species forage needs of Bay predators (osprey, bald eagles, and striped bass) rather than treating our enclosed estuary as an unconstrained single-species fishery.

Seasonal Quota Distributions: Restricting purse-seine reduction harvest during critical chick-rearing months (April through June) will eliminate direct resource competition when fledglings require the highest caloric density to avoid nest mortality.

Nearshore Spatial Exclusions: Industrial reduction vessels must be moved out of sensitive shallow bays, river mouths, and nursery zones into the open Atlantic, stopping commercial fleets from wiping out local schools in primary osprey hunting depths.

Option B4 — 50% Cap Reduction (25,500 MT): Lowering the cap will leave tens of millions of pounds of schooling biomass inside the Bay to sustain predatory fish and raptors rather than fishmeal processing.

Please vote for Option B4 and implement seasonal quotas to safeguard the Chesapeake Bay's maritime heritage and living resources.

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

I am writing as a waterfront landowner of over a decade on the Chesapeake Bay and an active wildlife photographer to strongly urge the Board to adopt Option B4 (a 50% reduction in the Chesapeake Bay reduction cap to 25,500 metric tons) and establish seasonal quota distributions under Draft Addendum II.

For more than ten years, I have documented the seasonal rhythms of the Chesapeake through my lens. In earlier years, tracking hunting ospreys was simple: dense, "boiling" schools of Atlantic menhaden regularly dimpled the surface across our creeks, coves, and shoals. Today, those vibrant bait balls are an increasingly rare sight, and my camera now records a distressing ecological collapse.

Atlantic menhaden are the vital caloric engine powering the Bay's entire food web. Without this forage base, our iconic raptors are starving. Across multiple seasons, I have watched returning pairs expend exhausting energy searching barren shallows, only to return with inadequate prey. Nest platforms that once reliably fledged two or three vigorous chicks now stand abandoned, or worse, harbor fledglings that slowly perish from nest-level starvation. Coastwide stock models showing "healthy" biomass completely fail to reflect the severe, localized depletion inflicted by industrial reduction fishing in the Bay's most vulnerable nursery shallows.

To reverse this crisis and protect our wildlife, I ask you to enact the following measures:

Option B4 — 50% Harvest Cap Reduction (25,500 MT): Slashing the reduction cap in half will keep tens of millions of pounds of essential forage biomass inside the estuary for predatory fish and raptors rather than fishmeal and oil rendering.

Bay-Specific Ecological Reference Points (ERPs): Quotas must be set based on the verified forage requirements of Bay predators—including ospreys, eagles, and striped bass—rather than single-species biomass models that treat this fragile estuary as an unconstrained fishery.

Seasonal Quota Windows: Purse-seine reduction operations must be restricted or delayed during peak chick-rearing months (April through June), directly eliminating food competition when young broods require maximum caloric intake to survive.

Nearshore Spatial Exclusions: Industrial reduction vessels must be prohibited from netting in shallow bays, river mouths, and nursery shoals, shifting operations into the open Atlantic and preserving shallow waters where ospreys dive.

The Chesapeake Bay cannot sustain the relentless removal of its keystone forage species. Please vote for Option B4 and implement strict seasonal quotas to protect our ospreys, our fishery, and the legacy of our waters.

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you recognize the sender and know the content is safe.

I am writing as a concerned waterfront landowner along the Chesapeake Bay to urge the Board to adopt Option B4 (a 50% reduction of the Chesapeake Bay reduction cap to 25,500 metric tons) and implement seasonal quota distributions under Draft Addendum II.

Living along these shores, I have witnessed a heartbreaking ecological shift firsthand. Where broad, "boiling" schools of Atlantic menhaden once rippled the shallows throughout the spring and summer, sightings have grown alarmingly scarce. Most distressing is the visible crisis among our resident ospreys. Menhaden serve as the primary caloric engine of the Chesapeake Bay's food web. In recent nesting seasons, platforms that once reliably fledged healthy chicks now sit empty or host broods that starve in the nest. Industrial "reduction" fishing—scooping up massive schools to grind into livestock feed, aquaculture pellets, and omega-3 supplements—causes severe localized depletion in the very foraging grounds these raptors depend upon. Coastwide biomass calculations mean little when localized foraging grounds are left empty.

To protect the wildlife, nursery habitat, and communities that depend on a healthy Bay, I ask you to approve:

Option B4 — 50% Cap Reduction (25,500 MT): Slashing the industrial cap in half will keep tens of millions of pounds of lipid-

rich biomass inside the estuary for breeding raptors and predatory sportfish like striped bass, rather than sending it to industrial rendering vats.

Seasonal Harvest Windows: Purse-seine reduction operations must be restricted or delayed during peak chick-rearing months (April through June). This eliminates direct food competition during the exact window when young fledglings require the highest caloric volume to avoid nest mortality.

Nearshore Spatial Buffers: Large-scale reduction vessels must be excluded from sensitive shallow bays, river mouths, and nursery shoals, moving industrial harvest into the open Atlantic and out of the critical dive zones of nesting ospreys.

Bay-Specific Ecological Reference Points (ERPs): Management must explicitly account for the forage needs of Bay predators (osprey, bald eagles, striped bass, and marine mammals) rather than relying on single-species yield models that treat the estuary as an unconstrained fishery.

The Chesapeake Bay is our nation's premier estuary and an indispensable nursery ground. Please honor the intent of the public comment period ending October 9, 2026, and vote for Option B4 alongside seasonal quota protections to safeguard the future of our ospreys and the Bay's broader food web.

In order to save what remains of our CB natural resources, we, the citizens of Virginia and concerned recreational fishermen, request that lower catch limits (or a moratorium, on tge menhaden fishery be put into place as soon as possible. Consideration should also be made to limiting more of the catch just outside of the mouth of the CB, out into the ocean.

We are sick and tired of decades of a Canadian company, Omega Protein, exploiting natural resources of the CB and the state of Virginia.

I am writing in support of stronger protections for Atlantic menhaden in the Chesapeake Bay and thoughtful consideration of the options before the Atlantic States Marine Fisheries Commission in Draft Addendum II.

Across Maryland and Virginia, communities and lawmakers have invested enormous time, energy, and resources in restoring and protecting the Chesapeake Bay. In this day and age, we have the technology, scientific knowledge, and community commitment to continue do better - not worse - for this vital ecosystem.

It is a tragedy to see wildlife like Osprey suffer from a lack of the food resources, in an era when we have the ability to understand these systems and manage them responsibly. In 2026, Osprey saw a staggering, record loss of offspring due to starvation. Menhaden are an important part of the Bay's entire food web, and the current Addendum process actively recognizes concerns about the quantity of menhaden harvest and potential downstream effects on crucial ecosystem predators.

Our communities should not have to choose between a healthy Bay, sustainable practices, or productive fisheries. We need our lawmakers and fishery managers to work with the people who care for this watershed. This should be a partnership based

on sound science, transparency, concern for the environment, and mutual cooperation.

I urge the Commission and our elected leaders to hear the communities of Maryland and Virginia and take meaningful action to ensure that the Chesapeake Bay has enough menhaden to sustain the wildlife and ecosystem we have all worked so hard to restore.

I have lived on the Chesapeake Bay for over 50 years now and one of my favorite times of the year is around St. Patrick's Day because around this time is when I can see the return of Ospreys to our area. This year I noticed a dramatic decline in the number returning. Not only the osprey but also numerous other species in the bay depend on the menhaden for their survival. Please put a cap on the netting and removal of menhaden in the Chesapeake Bay. The survival of not only the Osprey but also the entire bay depend on putting a stop to the removing of the menhaden from our waters.

I am writing in strong support of the most protective options in Draft Addendum II for Atlantic menhaden management in the Chesapeake Bay. Menhaden are the foundation of the Atlantic coast's marine food web and are critically important to striped bass, bluefish, weakfish, ospreys, bald eagles, marine mammals, and many other predator species. The Chesapeake Bay serves as one of the most important nursery areas for Atlantic menhaden, making conservation of this resource especially important.

I urge those in consideration to adopt the largest reduction under consideration for the Chesapeake Bay Reduction Fishery Cap. The current draft recognizes concerns about concentrated industrial harvest within the Bay and the potential ecological impacts of removing large quantities of forage fish from a critical nursery ecosystem. A meaningful reduction in the Bay cap would better protect the Bay's food web, provide more forage for predators, and reflect the ecological importance of this area.

I also support linking the Chesapeake Bay cap to the coastwide total allowable catch so that reductions and increases occur proportionally over time. This approach would provide a more consistent and precautionary management framework and ensure that Bay protections keep pace with future changes in coastwide management.

In addition, I support establishing quota periods that distribute harvest more evenly throughout the fishing season. Concentrated harvest during key periods can have disproportionate impacts on predator-prey relationships and on other fisheries that depend on healthy menhaden availability. Spreading harvest across the season is a commonsense measure that can help reduce localized depletion concerns and lessen ecosystem impacts.

The Chesapeake Bay is the only place on the Atlantic coast where a large-scale reduction fishery continues to target menhaden for fish meal and fish oil production. Given the Bay's ecological significance and the growing concerns from anglers, conservationists, and other stakeholders, the Commission should act conservatively and prioritize ecosystem health over short-term harvest opportunities.

Thank you,

Kacie Collins
Annapolis, MD

Please help the Ospreys and all the other interconnected life forms!

Dear ASMFC Atlantic Menhaden Management Board,Thank you for the opportunity to comment on Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden.I am writing to express my support for taking meaningful action to protect Atlantic menhaden populations, preserve local ecosystems, and support balanced user groups along the Atlantic coast and the Chesapeake Bay.Chesapeake Bay Reduction Fishery Cap (Bay Cap): I support reducing the Bay Cap. A reduction of up to 50% is a critical step toward preventing concentrated fishing pressure in the Chesapeake Bay. Lowering the cap helps protect local predator species—such as striped bass and ospreys—that rely heavily on menhaden as a primary food source.Quota Periods and Distribution: I support establishing distinct quota periods. Spreading the harvest more evenly across the fishing season rather than exhausting the cap too quickly prevents intense localized depletion and reduces gear conflicts with other fisheries.Setting the Cap as a Proportion: [Choose one: I support / I do not support] setting the Bay Cap as a fixed proportion of the coastwide total allowable catch, ensuring that management scales dynamically with the coastwide stock status.Thank you for your time, dedication, and consideration of sustainable management practices for this vital forage fish.

It seems counter intuitive to try to manage all of the predator species that prey on menhaden without addressing the overfishing of menhaden in the chesapeake bay. It seems pretty clear to me that the striped bass numbers in the bay are related to a reduction in foraging species.

I support the proposal to cap the Chesapeake harvest by a full 50% and establish seasonal quotas to spread out the catch until we have a full understanding of the Chesapeake's role as an ocean nursery. A brief history of Atlantic Coast fisheries reveals resource economics and long-term sustainability exist in a fragile, never-ending balance. Most notably, the complete collapse of New England's cod fisheries in 1992-93 and its enduring effects on populations of haddock and flounder. Despite decades of strict U.S. limits, cod remains ecologically collapsed while haddock and flounder show fragmented recoveries and re-collapses.
In the 1960s-70s along the northeast coast, the menhaden industry collapsed as a result of overharvesting, effectively wiping out the reduction factories in New England and leaving only a highly regulated pocket in the Chesapeake Bay. At the same time, overfishing of Atlantic mackerel off the U.S. coast led to a population crash. Today, the commercial mackerel fishery faces near-total closures and strict rebuild mandates. Other high-profile collapses resulting from overharvesting include 19th century collapses of Eastern oysters and Atlantic halibut.
In the long run, conservation is less costly than restoration. By acting conservatively, you are actually protecting future harvests and jobs. Thank you for your dedication to the health of our fisheries.

I support sub options
3.1 B4
3.2.1 B1 for harvest time
3.2.2 option 1
3.3 option B

T think there also need to be a 30 percent cut to the ocean stock. I think the commercial harvesters should pay bock the past quota overages

Dear Members of the Atlantic Menhaden Management Board,
My name is Fletcher Chayes, and I am a 30+ year charter boat captain in Monmouth County NJ. I am writing as a regular user of our coastal waters to express my strong support for Option B (a 50% reduction in the Chesapeake Bay reduction cap) and the implementation of Seasonal Allocations under Draft Addendum II to Amendment 3.
I have witnessed, first hand, the negative effects of the lack of menhaden in our waters. There are very few menhaden in our waters and there are not multiple year classes. More times than not there AREN'T any in our waters. This has had a negative impact on my earning a living chartering. So much so I have had to diversify my income earning ability. I have witnessed adult osprey carrying palm size menhaden to their nests for their chicks. Not near big enough meal for the chicks. A look with the binoculars confirms the chicks died. No food no life. The current industrial reduction cap of 51,000 metric tons allows an unsustainable concentration of harvest within the delicate nursery grounds of the Chesapeake Bay. This has led to severe localized depletion, which directly threatens the foundational health of the entire ecosystem.Leaving more menhaden in the water is absolutely critical for the following reasons:
Apex Predator Recovery: Our most iconic sportfish, the striped bass, is struggling. Without an abundant, reliable food source like menhaden, coast wide rebuilding efforts for striped bass will continue to falter.
Avian Wildlife Protection: Localized depletion has had devastating, visible impacts on our regional osprey populations, with

scientists documenting widespread nesting failures and starving chicks due to a lack of menhaden.
Broad Economic Value: While the reduction fishery supports a concentrated industry, a healthy, bait-rich Bay supports a far larger and more diverse economy. Thousands of livelihoods depend on this ecosystem, including recreational anglers, charter boat captains, local crabbers, and coastal ecotourism businesses.Furthermore, implementing seasonal allocations is a necessary step to stop industrial fleets from wiping out entire generations of baitfish in short, concentrated summer windows. Spreading the harvest out ensures that wildlife and local watermen have access to forage fish throughout the active season.
I urge the Board to prioritize the long-term ecological balance of the Chesapeake Bay and the thousands of communities that rely on it by enacting the maximum conservation measures in Draft Addendum II.
Thank you for your time, leadership, and consideration of my comments.
Sincerely,
Capt. Fletcher Chayes

The Osprey population is being decimated by overfishing. The hatchling rate of Ospreys along the Connecticut River is dramatically reduced this year, to almost nothing. It is critically important that the menhaden catch quota be drastically curtailed. Action must be taken now. Do not allow human greed to obliterate this graceful species.

I support:

(1) Up to 50% reduction on menhaden fishery limits so there should be more food for ospreys

(2) Spreading out the fishing season to avoid stress in the spring and summer, when the ospreys breed and feed their chicks.

To Whom It May Concern,

I am writing to urge the Atlantic States Marine Fisheries Commission and state regulators to implement stricter management policies and significantly reduce industrial menhaden harvesting in the Chesapeake Bay and its tributaries.

As a frequent kayaker on the Patuxent River, I have a direct, firsthand view of our local ecosystem. Over recent seasons, I have observed a deeply concerning decline in the number of ospreys along the river. Where I used to reliably see thriving pairs and active nests, I now see empty nests and far fewer birds hunting.

The connection between industrial menhaden reduction fishing and the starvation of osprey chicks is well-documented. Menhaden are the vital, high-energy foundation of the Chesapeake Bay food web. When industrial purse seine vessels deplete these localized fish populations, the impacts ripple upward immediately. Ospreys simply cannot find enough food to sustain themselves or successfully fledge their young.

Personal observations like mine along the Patuxent River are matching what scientists are finding across the region: our

ospreys are in crisis.

I urge you to prioritize ecological management over commercial reduction fishing interests. Please establish stricter catch limits, move industrial reduction fishing out of the Bay entirely, and ensure that enough menhaden remain in the water to support the ospreys and other wildlife that rely on them.

Thank you for your time and consideration of these comments.

Sincerely,

Taryn Sanders

I fully support drastically limiting the annual Menhaden fishing. Today sport fishing is capped and my fellow sport fishers have been following those rules for years. It's time for commercial fishermen to do the same.

There are multiple renewable agricultural sources of protein and omega 3 fatty acids. We need to support these renewable resources and stop depleting our natural fishing stocks before it is too late.

I Fully support the 50% reduction in the Chesapeake Bay reduction fishery cap (Option B4-reducing the cap to 25,500 metric tons) AND support for seasonal quota periods.

I have lived and recreated on the bay my entire life, and I care about the health of the bay ecosystem.
The sharp decline of osprey nest success is very alarming. I personally have 3 osprey nest platforms on my waterfront property, and for the past 4 years there were NO successful nestling fledges. The past two years the adults did not even stay at the nest platform. This is alarmingly concerning and calls for immediate action to help recovery in whatever way necessary. The lack of adult menhaden fish which provides the vital nutrients these birds need to survive is most likely a major reason the osprey population has crashed in the Chesapeake Bay area.
The Chesapeake Bay once had the largest population of ospreys in the United States. Not anymore.

Industrial fishing taking over 100 million pounds of fish in the summer season, disrupts the local food web and deprives watermen, fishermen, tourism fair access.
I urge you to implement strict quota periods which distributes harvest evenly across the year instead of an intense summer

harvest.
Thank You,

“ASMFC itself says its existing models cannot determine whether localized depletion is occurring within individual portions of the menhaden’s range, including the Chesapeake Bay.

That uncertainty should lead to better research.

It should lead to better monitoring.

It should lead to conversations about when and where fishing occurs, how harvest can be distributed throughout the season, how predator needs should be considered and what level of harvest is sustainable.

What it should not automatically lead to is the conclusion that hundreds of years of Northern Neck fishing heritage should disappear.

Protect the Bay and the people who live here.

I don’t want an unhealthy Chesapeake Bay.

The fishermen don’t either.

Their livelihoods depend on healthy water and healthy fisheries perhaps more directly than almost anyone criticizing them from behind a keyboard.

We should absolutely demand responsible fishing. We should demand compliance with environmental laws. We should continue improving the science used to manage menhaden.

But protecting the Chesapeake Bay should also mean confronting agricultural runoff, stormwater, wastewater, shoreline degradation, development and the many other pressures affecting this enormous watershed.

And when regulators consider another reduction in menhaden harvest, the families of Reedville and the Northern Neck should not be treated as collateral damage.

Protect the fish. Protect the Bay. But protect the people whose lives have depended on that Bay for generations, too.

That is what balance actually looks like.”

Without proper study instead of survey or matters of opinion no policy or decision should be made that would hurt those who rely on the fisheries. Do not let this be decided by emotion before facts.

I've noticed a big decrease in the number of Osprey that we usually see flying above our local waterways. Their absence is of great concern. I've read about the connection between Atlantic Menhaden and our iconic shorebirds and request that your commission use your power and position to act now to slow/stop this unfortunate decline. Please put a moratorium on removing menhaden from the bay and surrounding waters. If you can't stop them from being removed, at least put strict limits on the amount of menhaden that can be taken. The loss of menhaden is terrible environmental problem and you are able to act and tackle this problem.

I have lived on the waters of Maryland's Eastern shore for 44 years. First hand I have seen the decline in fish and birds (Osprey) on the Eastern shore of Maryland in our area of the Miles River. As a Marine Fisheries Commission I would hope that you have longer ranged implementations for OUR wildlife's future. Wildlife that has been stressed by so many factors have rebounded and greatly benefitted from either moratoriums or catch(bag) limit decreases.

Please make adjustments concerning the TONNAGE catch limits on Menhaden for the future existence of OUR wildlife. Giving wildlife time to rest and rebound is a momentary interruption that has been proven to be extremely beneficial. Please make adjustments before there is no need for a Commission due to no fish or wildlife.

Thank you

Whales, Osprey, Tarpon, Striped Bass, Bluefish and many other animals depend on a healthy stock of Menhaden. However, Menhaden have been severely overfished. Osprey are starving. I have witnessed this firsthand. Marine mammals and fish are also being impacted. A complete closure to the commercial fishery should be enacted until the stock is completely recovered to historic levels. The resource should come first. Get the politics out of the equation. The employment provided by the commercial fishery is quoted at around 270 individuals and hardly compares to the employement impacts of a healthy Menhaden stock in the Atlantic and the Gulf. Forget the notion of a Menhaden surplus. That approach has helped to get us where we are now.

Greetings,
I have the pleasure of watching and hearing osprey hunt near Harbor Light in New London, CT. They will sit atop the railing of the lighthouse and watch the water below. Their beautiful plumage, alert eyes, and high pitched chirps are a delight to observe. I see their amazing head first dives into the water and the power of their wings as they strive to pull back up into the air. I always check the little shake off of water and the talons to see if dinner was caught. I also note how many attempts are made, sometimes as many as 5 dives to procure one small
fish and more frequently after searching and diving, they leave without catching any fish. They are such hard working birds of prey and are chased by gulls for their little fish which the osprey will drop for the gulls to take. Once I saw an smaller osprey catch a fish too large to carry and he drug it across the rocks with the talons of one foot. As the osprey started to eat his big meal, he constantly watched the sky and soon gulls came and dive bombed the osprey. The osprey abandoned his meal and cried above the scene as his food disappeared. The large gull took the fish in the water and devoured it quickly.
I also watch the plentiful cormorants, terns, and gulls follow the schools of bait fish, feasting on them along the coastline. From my perch, I also see the commercial fishermen with their nets dragging behind their boats frequently. There are also small skiffs laying nets out near the shore, and coming back the next day for the harvest. It is no surprise that with all the stress on the aquatic environment, the osprey are losing their ability to feed their young.

We must recognize their struggle to survive and place controls on human harvest of the very important menhaden's position in the food chain.

I am an active recreational fisherman in NJ coastal waters. I have observed a significant reduction in menhaden schools last year and this current season. I would support a significant reduction in the menhaden quota across all waters. I would also advocate for a possesion limit of peanut bunker for bait by recreational anglers on the order of one gallon, having observed the netting of thousands of juvenile bunker by individual fisherman for chum.

As an avid recreational fisherman based in NJ, I am writing to urge the Atlantic Menhaden Management Board to adopt a significant reduction in the overall commercial Atlantic menhaden quota across the coastwide fishery not just the Chesapeake Bay. Menhaden are not simply a harvested commodity; they are a foundational forage species that supports striped bass, bluefish, weakfish, seabirds, marine mammals, and the broader health of the Atlantic coastal ecosystem.
ASMFC has already recognized the importance of ecological reference points in menhaden management, and recent management discussions indicate that current harvest levels may remain above the level needed to meet ecosystem-based targets. A modest reduction is not enough if the goal is to rebuild forage availability, support predator recovery, and reduce the risk of localized depletion in important areas such as the Chesapeake Bay and other nearshore waters.
I respectfully ask ASMFC to take a precautionary, ecosystem-first approach by substantially lowering the total allowable catch for commercial menhaden harvest across all jurisdictions, rather than relying only on narrow area-specific adjustments. A coastwide reduction would better reflect menhaden's role in the food web, help ensure adequate prey availability for dependent species, and demonstrate that forage fish management is being guided by long-term ecosystem resilience rather than short-term extraction.
Commercial fishing communities deserve thoughtful transition planning and fair implementation, but those concerns should not prevent meaningful conservation action where the science and ecosystem risks point to the need for stronger limits.

Menhaden abundance benefits many sectors, including recreational fisheries, wildlife-dependent tourism, coastal communities, and the long-term sustainability of commercial fisheries themselves.
For these reasons, I urge ASMFC to adopt a significant coastwide reduction in the commercial Atlantic menhaden quota and to continue advancing ecosystem-based management measures that protect menhaden as a critical forage species. Thank you for the opportunity to comment.

I strongly support reducing the Chesapeake Bay reduction-fishery cap by 50 percent—from 51,000 metric tons to 25,500 metric tons per year—and establishing strict seasonal quota periods for menhaden. The Chesapeake Bay is too important, and the ecological warning signs are too serious, to continue managing this critical forage fish as though the timing and location of harvest do not matter.
I have lived in St. Mary’s County since 201 and have developed a deep personal connection to the Chesapeake Bay. I spend considerable time on and around the Bay. I care deeply about the wildlife that depend upon it, particularly osprey, striped bass, and other species whose survival is tied to a healthy and abundant forage base.
We are seeing warning signs that should demand a precautionary response. Declining productivity, widespread osprey nest failures, and continuing concerns regarding the Chesapeake Bay striped bass population are not isolated issues. They are reasons to examine carefully whether we are removing too much forage from the Bay at the wrong time and are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - menhaden.
Menhaden are a foundational forage species. They feed an extraordinary range of predators, including striped bass and osprey. Yet the reduction fishery can remove more than 100 million pounds of menhaden from Chesapeake Bay under the existing annual cap. When a substantial portion of that harvest is concentrated into an intense summer fishing window, the issue is not simply how many fish are removed annually.

It is both when and where those fish are removed that matter. A menhaden harvested from a concentrated school in the Bay during the summer is no longer available to the predators that depend upon that school. Concentrated removal can create localized depletion during a biologically important period and can affect the availability of forage to other users of this shared public resource.
The consequences extend beyond the reduction fishery. Menhaden support the Bay's recreational fishing economy, commercial and charter fishermen, watermen, wildlife, and coastal tourism. One user group should not be permitted to concentrate an enormous harvest of a shared forage resource during the period when that resource is most important to the rest of the ecosystem and to other Bay users.
For that reason, I urge the Commission to take the following actions:
• Reduce the Chesapeake Bay reduction-fishery cap by 50 percent to 25,500 metric tons annually.
• Establish strict seasonal quota periods that distribute harvest throughout the year rather than permitting an intense summer harvest.
• Apply a precautionary management approach in light of uncertainty regarding localized menhaden abundance and the ecological condition of the Chesapeake Bay.
• Give greater consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the broader Chesapeake Bay economy.
The Chesapeake Bay is not simply a location on a fisheries management map. It is a complex and interconnected ecosystem, and menhaden are one of its essential links.
We should not wait for further deterioration before taking action.
As someone who lives here, sails these waters, swims in them, and cares deeply about the wildlife that depends upon them, I believe the Commission has an obligation to manage menhaden conservatively and to recognize that the health of the Bay must take precedence over maximizing a concentrated industrial harvest.
Reduce the cap. Establish meaningful seasonal quotas. Protect the forage base. Give the Chesapeake Bay—and the people and wildlife that depend upon it—a greater margin for recovery.
Thank you for considering my comments.
Sincerely,
Howard Kympton
St. Mary’s County, Maryland

I write to urge the commission to take strong action to protect the Atlantic Menhaden fishery. Specifically, I support the following changes options in the pending draft addendum:

3.1 Chesapeake Bay Reduction Amount: Sub Option B4

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period: Option B1

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages: Underage Sub Option 1

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Option B

Additionally, the coastwide TAC must be further reduced by at least 50%, but not less than 30%.

Reduction fishing for Menhaden or any fish should not be allowed in our state waters.
No other states on the east coast allow this to occur in their state waters and neither should we, especially by a non US company.

As an avid fisherman and also an Osprey Watch volunteer, I am appalled at the lack of action taken by the AMSFC (or inadequate action) to protect this vital natural resourse. It appears that money and power are more important than the pulblic's interest in our fragile environment. I sincerely hope that you do the right thing and accept a 50% reduction in the number of Manhaden catch in the very near future.

Dear Commissioners,

I live on the Upper Magothy River in Pasadena, Maryland. Each year the ospreys arrived in March and their chirping could be heard throughout the neighborhood until September. We had several pairs on our small stretch of the river, and they were visible all summer. We also had fish activity all summer long. Last year the nest the ospreys built on our platform failed. This year, there were no osprey nests in our stretch of the river, and downstream, the few nests that were attended failed. We also noticed a dramatic decrease in fish activity. We cannot ignore these warning signs. Please protect the menhaden, which support life in the bay and its tributaries.
Sincerely,

Kelly Tubman Hardy.

I support a 50% reduction in the Chesapeake Bay reduction fishery cap and support seasonal quota reductions periods. I'm from Pennsylvania, but I visit family in Maryland several times per year. May wife's parents have a house on the Chesapeake Bay, so we stay at their house for extended weekends. We spend most of our time outside enjoying the Bay. Bird watching is one of our favorite things to do, but I have noticed a drop in Osprey and other predator species over the last couple of years. I believe it's related to the heavy amount of industrial fishing- especially concentrated in the summer months. This is why I'm supportive of Option B4, which reduces the fishery cap. I believe this will help reduce overfishing and allow predator species like Osprey thrive again. Thank you for taking the time to read my comment - and for your consideration to help preserve this precious piece of nature.

All public resources should be preserved for that of the public, for “personal use”. Not for commercial / corporate gain. Commercial
Fishing has devastated sought after fish stocks, allowing that same system to destroy bait fish stocks to feed commercially farmed fish because when they already decimated natural fish stocks makes absolutely no dam sense.

Commercial fishing for menhaden should be abolished except for use as bait by sports fishing. It makes more economic sense to restore menhaden in order to support higher value sport fishing. In addition, to higher value tuna, swordfish, stripers and other sport fish that depend on menhaden so do marine mammals and osprey.

I am writing to urge the ASMFC to take immediate, strong action to protect the Chesapeake Bay ecosystem by implementing strict catch limits under Atlantic Menhaden Draft Addendum II. Specifically, I support options that substantially lower the reduction fishing allowance in the Bay.

As a resident/supporter of the Chesapeake Bay region, I am deeply alarmed by the unprecedented breeding failures and starvation currently devastating our local osprey populations. I am a volunteer with the Chesapeake Bay Environmental Center's Project Osprey Watch, and we have witnessed the collapse of the osprey population that we monitor at CBEC. In 2026, we had 4 of 9 platforms populated, three nests had ospreys on eggs, and shortly thereafter, all platforms/nests were abandoned. We had NO osprey hatchlings this year. Nor did we see any successful nests in the entire Kent Narrows area. Our observations concur with decades of scientific monitoring that show a direct link between the lack of mature Atlantic menhaden and the inability of ospreys to successfully raise their chicks.

Menhaden are the ecological backbone of the Chesapeake Bay--a keystone species. Allowing industrial-scale reduction fishing to deplete this critical forage fish at the expense of ospreys, striped bass, and other native wildlife is unsustainable and unacceptable.

Please prioritize the long-term health of the Bay's ecosystem over short-term commercial harvest by implementing the maximum possible protections in Draft Addendum II. Thank you for your time and consideration of these comments.

The depletion of Menhaden in the Chesapeake is very troubling. I fear the failure to reduce the catch will make matters even worse for the incredibly diverse body of marine life that depend on them for their survival, including stripped bass, bluefish, sea trout, tuna, cod, sharks, whales, dolphins as well as many species of birds from fish hawks to gannets.

The fishermen will say they're not the problem. It's the seals or the cormorants, or some other excuse to do anything that affects the bottom line.

You have the responsibility to ensure the sustainability of these species. I urge you to do the right thing and reduce the human impact. Reduce the cap.

Respectfully, Rav Freidel, Montauk, NY

Menhaden harvest should be more than a spreadsheet projection. Does 50% reduction mean the population is the same? Should harvest be based on the number of fish present? Maintaining a healthy breeding population seems more important. Perfect net doesn't catch all the fish

I am in favor of significantly cutting menhadden harvests in the Chesapeake Bay. It is obvious that damage has been done as can be seen in the striped bass and osprey populations. This has persistently been fought by groups connected to the menhadden processing industry. First they helped pass a bill to prevent studying the problem, and now they want to delay things until it can be 'scientifically' studied. Their time is up. Injury has occured, and it is time to both decrease the harvest and study the issues further.

Dear ASMFC:

I am sending this comment in extremely strong support for a 50% reduction in the Chesapeake Bay reduction fishery cap. (Option B4/reducing the cap to 25,500 metric tons) and support for seasonal quota periods.

As a long time resident of Drum Point in Calvert County, MD I have enjoyed the beauty and health of our Chesapeake Bay and its tributaries. I reside on Mill Creek right around the corner from Solomons Island harbor. We have numerous osprey nests on the creek that used to be filled with active parents and their young. We would throw sticks in the back yard and watch the osprey swoop down to scoop them up for nest repair. We wanted to ' give them a hand' so to speak as they work so hard to build their nests to provide a safe haven for raising their young. The wonder of these tremendous raptors never ceases to amaze me and the fear of their disappearance sickens me. We witnessed an abandoned chick in the Leason Cove nest where the parents had to leave their young babe in order to survive themselves.

The industrial concentration extracts over 100 million pounds of fish in one summer window. This is the most precious time for osprey as their reproductive season is severely comprised by the lack of nutrient rich Menhaden. Their young are born weak,

if at all, and they suffer and die due to starvation and dehydration. We had only 4 surviving chicks in our area and I remember when every nest was occupied with young years ago.

The widespread failures among the osprey and stressed populations of striped bass is a signal for dramatic and swift action. The fact that these industrial conglomerates extract such an enormous amount of a life supporting food source MUST be reined in and managed to allow fair access for all to benefit. We must protect this delicate ecosystem as we are merely visitors here and want our future generations to be able to enjoy the beauty of a healthy and prosperous Chesapeake Bay.

I am urging managers to PLEASE implement strict quota periods that will make a significant impact for our osprey and marine life. Distribute the quota across the year rather than allowing an intense summer harvest severely depleting a food source for so many species that need it to survive.

Extremely Concerned Citizen on Mill Creek in Calvert County, MD

I live all summer on Fire Island. It was quite clear that the amount of bunker this year was well below what we've seen in recent years.
I read that we allowed these giant Canadian vacuum ships to suck up vast quantities from our waters. These fish need to be led to feed the other marine life like the dolphins and whales and even sharks.
They need to be left to feed the birds.
It's time to stop killing this world by destroying key parts of the food chain!

I'm on Wright's Cove off the Coan River and in my thirty years here it is clear the bay waters have been depleted of wildlife. This is not just my opinion. It comes from discussions all around the Chesapeake. The belief is that we have become too efficient at cleaning the fish out and we must back off. If we want healthy fish, we can't take them all out.

It's criminal that one company gets gets most of the catch. And that most of the catch goes to just one State. C'mon, it just doesn't make any common sense. At the very least distribute it around.

The negative effects of the commercial reduction fishery are apparent to any observer who has spent any time on or around the Chesapeake Bay over just the past few years.

My personal experience over the past 26 years living near a Western shore river has seen a significant decline in the abundance of menhaden in the Bay and its tributary rivers. Where once the surface of the rivers teemed with baitfish, and their attendant flocks of birds feeding from above and predator fish species feeding below, the waters now are still.

It is clear, too, that the species that depend on these important fish as food are struggling as well. Abundance of Striped Bass, whose species has historically been centered on fertile spawning grounds in the Chesapeake have declined dramatically. Osprey, who have returned each year, with generation after generation roosting on the channel marker just off our neighborhood's shore successfully spawned year after year, but have failed to produce offspring in each of the last 5 years.

The commercial reduction fishery is not the only contributor to the Bay's decline, but it is clear to me that their massive

removal of important biomass from the Chesapeake Bay, and the removal of these important filter feeders that clean the Bay's water, has had tremendous negative impacts on the Chesapeake Bay and all who call it home.

I would like to see the Atlantic states adopt the Maine model by enforcing a forage fish sanctuary off our coasts. Let nature heal to abundance, not just manageable numbers. The industry that is pillaging the fishery is a foreign company, for profit, affecting fewer than 250 people.
While we, who want serious change represent taxpayers and citizens providing millions of dollars of money as well as hundreds of jobs going into our local economies. Thousands of recreational fishermen and women see firsthand the very real effects of over fishing....
Change is hard but necessary.....do the right thing for nature and let her heal.....and find a balance..... She will, with your help.....Thank you.... JR

Stop menhaden over-harvesting in the Chesapeake Bay. We have one Bay. One chance to save this critical ecosystem. Do not be distracted by the almightly dollar. It has been proven that the value of keeping menhaden in the Bay is far more profitable and beneficial then taking them out of the Bay.

As a decision making body you can not sit back and watch the largest estuary in the country be raped by less then 300 jobs sending our most valuable forage fish to a foreign country to feed a farm raised fish while taking the native fish out of the mouths of our natural resource.

The Bay belongs to the public. It is not a monoply to be manipulated by Omega protein.

Over the last year I have followed the story of the decline of osprey numbers in my home state of Connecticut. It is upsetting to see such a dramatic decline. These birds are a vital part of our environment. Commercial fishing limits need to be put in place to make sure important resources are shared with other aspects of our environment. We see so many ways human greed and selfishness is ruining the nature around us. Please do something to help limit human damage of a known and solveable problem.

As a Board member and volunteer at the Connecticut Audubon Society Coastal Center, as well as a Master Wildlife Conservationist, I urge the AAMFC to put a 50% cap on the capture of menhaden along Chesapeake Bay and the Atlantic coast so our osprey population isn't starving to death. Ospreys had made a major comeback after the banning of DDT use. Now the ospreys numbers have had another major decline because there is not enough food (primarily menhaden) for them. As a steward for Osprey Nation, Connecticut recorded its lowest breeding success since the Osprey Nation launched its monitoring program in 2014. Ospreys are part of America's majestic wildlife and we must protect them! Humans can consume any number of fish but Ospreys rely on a steady supply of menhaden to feed their chicks. A 50% cap on the capture of menhaden must be passed to ensure our Osprey population will bounce back and continue to thrive!

The Atlantic States Marine Fisheries Commission is considering changes to the amount of menhaden that can be commercially harvested from the Chesapeake Bay. I personally have watched 3 osprey couples return to the marsh near my home to raise offspring each year for several years now. However, friends tell me that they have seen a decline in returning couples and viable offspring in their areas. I agree with the position of Connecticut Audubon -- this organization (of which I am a member) is urging the commission to reduce the fishery cap by 50% to help ensure enough menhaden remain available for Ospreys and other wildlife.

To protect the Bay's ecological integrity, I strongly advocate for the following specific options:Section 3.1 – Chesapeake Bay Cap Amount: Support Option B4 (50% Reduction in the Bay Cap). The Bay Cap must be cut immediately from 51,000 mt to 25,500 mt. Menhaden serve as the fundamental food base for ecologically and economically vital species such as striped bass, bluefish, weakfish, and osprey. Concentrated industrial removals deprive these predators of critical forage in essential nursery grounds. Section 3.1 – Linking Cap to TAC: Support Option C1e. If the Board chooses to link the Bay Cap directly to the coastwide TAC, it must lock in the lowest possible proportion (13.6%) to ensure that future shifts in coastwide allocation do not allow localized effort in the Bay to expand. Section 3.2 – Quota Periods: Support Option B2 (Even Length & Uneven Harvest). Industrial fishing concentrated into short, mid-summer windows causes severe localized depletion and directly disrupts local traditional fisheries, including pound net operations. Restricting mid-summer removals (limiting early periods to 25% each) prevents Omega Protein from stripping the Bay of forage during peak ecological demand. Section 3.3 – Revisit Provision: Support Option B (Mandatory 3-Year Review). The Board must mandate formal re-evaluations of the Bay Cap every three years to continuously assess localized impacts and scientific data. The Chesapeake Bay is a nursery, not a private industrial extraction zone. Decreased localized catch rates, declining predator stock health, and severe losses in local bait and pound net catches all point to the urgent need for strict limits. I urge the Management Board to adopt the most restrictive measures available in Draft Addendum II to safeguard the Chesapeake Bay forage base.

My husband and I have enjoyed watching the Ospreys and their chicks over the years in the shoreline area of CT near Old Saybrook. We have been sad that the last couple of years, there have not been any chicks and understand that over-fishing in the Chesapeake Bay could be a cause of this. The state of CT worked very hard to nurture the osprey population, and now I believe there is a danger of a significant reduction in population. It would be a travesty to lose these magnificent birds and the joy they bring, in addition to their role in our eco system. Please help cap the fishing and support our osprey population. Thank you.

The science behind the need to limit the commercial harvesting of menhaden for Osprey (and other species') benefits is pretty clear: Ospreys nesting along the coasts where menhaden is being commercially fished are being grossly negatively affected. Menhaden being harvested for fertilizer and fish oil for human consumption is killing ospreys. It's clear. The harvest needs to be limited. It can't wait.

I wholly support a 50% reduction in the menhaden cap under consideration. This is actually long overdue. Osprey young are starving. Striped bass are not feeding as well and they then eat more blue crabs. Menhaden is the feeder fish of the ecosystem. So many livelihoods depend on a healthy menhaden population in the Chesapeake Bay. Management of this species should be science based and not a political decision based on political funding. Omega Protein has depleted the menhaden stock with massive nets and spotter plains. I beg you to act now!

I went on an Audubon Society trip to look at the swallow flocks on the Connecticut River, and there were far fewer ospreys than usual. Our guide showed us research indicating that southern ospreys have likely declined in recent years due to menhaden overfishing, and that it might be happening in Connecticut now. We must save ospreys before it is too late — reduce menhaden fishing now.

I request that you change/reduce the fishery cap on menhaden due to the serious threats facing osprey. It is particularly disheartening for their populations to be at risk again after such a wonderful comeback. I am sure you have seen the numbers from CT indicating a higher rate of failed nests. I monitor a nest and while it appeared to be active earlier in the summer it has now been abandoned. Watching the osprey thrive is a source of joy for so many people, even those who are not particularly interested in nature or birds. Please assist them so they can thrive once again. Thank you for allowing us to comment on this important matter. Diane Napert-Houle

I ask that there be limits on the amount of menhaden that can be fished. There have been significant reductions in the osprey and the amount of babies they had this year because the osprey did not have enough to eat because menhaden have been over fished. We have osprey in our backyard. This year they did not have any babies that lived. The 5 other osprey nests in our marsh also did not have babies this year. Thank you, Ken Skidmore

For the past 10 years we have been watching decades of conservation efforts erode. The Osprey is another casualty of we as a society becoming complacent in our minor success at restoration of a species. The money and effort of conservation should be seen as an investment and protected accordingly. No one takes their stocks,bonds and IRA to Atlantic City for weekend spree. They are our legacy and are fiercely guarded. Our wildlife are also our legacy and should be treated the same.

I have fished both the Chesapeake Bay and Ocean for over 60 years and have seen the rapid decline of many of our fisheries including striped bass and bluefish. Much of it is attributed to a lack of their primary forage fish menhaden. It is high time to take action now to conserve these important baitfish. I support the most conservative options to protect and conserve menhaden in the ASMFC Menhaden Addendum Draft II. This is what I support in the document:

3.1 Chesapeake Bay Reduction Fishery Cap Amount
I support option C1e: that reduces the CAP by at least 50 percent in 2027 and limits the future Bay Cap to 13.6% of the Coastwide Catch Limit (TAC).
Also, I support option C2a, which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.
3.2 Chesapeake Bay Cap Distribution
I support option B2, which establishes three even length quota periods for the Bay Cap, but distributes harvest 25% in period 1, 25% in period 2, and 50% into period 3.
Also, I support, option B, which establishes quota period overage payback and rollover of unused quota within a fishing year.
3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
I support the Option B Revisit Provision, to reassess the efficacy of these new management tools every 3 years.

Please take strong action now,
Thank you
Don Pirro

This is to inform you that I support the reduction of permitted commercial catch of menhaden in the Chesapeake Bay. I have seen a significant reduction in menhaden in Barnegat Bay and adjacent estuaries which I attribute to the overfishing. This in turn has had negative impact on other species in the bay's fisheries and wildlife, specifically the Osprey. Please help preserve the natural treasure of the Barnegat Bay by reducing commercial fishing of menhaden. Thank you, George Galdo 40 Robert Dr. Manahawkin, NJ 08050

Dear Members of the Atlantic States Marine Fisheries Commission,

I am writing to urge you to reduce the Chesapeake Bay menhaden fishery cap by 50%.

Ospreys are among the birds I most enjoy observing and photographing. As a nature photographer, I have spent many hours watching them hunt, interact, raise young, and return year after year to familiar nesting areas. Those experiences have given me a deep appreciation for how dependent these birds are on healthy coastal waters and an adequate supply of fish.

What concerns me most is the dramatic decline in nesting success that is now being reported in Connecticut.

By August 1, 2025, 113 of 706 monitored Osprey nests had failed, about one in six. During the same period this year, 171 of 691 nests had failed, approximately one in four. At Great Island in Old Lyme, one of Connecticut's historically important Osprey areas, 37 chicks fledged in 2024, 27 fledged in 2025, and only five fledged this year.

A decline of that magnitude should not be dismissed as ordinary year-to-year variation.

Ospreys are particularly valuable indicators of environmental conditions because fish make up nearly all of their diet. When adult birds cannot consistently find enough prey, the consequences are quickly reflected at the nest. Chicks may receive too little food, breeding attempts may fail, and population declines can follow.

Atlantic menhaden are an essential part of the coastal food web. They support not only Ospreys, but also other birds, predatory fish, and marine wildlife. They therefore have ecological value far beyond their commercial harvest.

I understand that fisheries management must consider many competing needs. Commercial fishing is important, and sustainable harvest is a legitimate goal. But sustainability should include the needs of the entire ecosystem, not simply the maximum amount of fish that can be removed without collapsing the target species.

When wildlife that depends on menhaden begins showing signs of severe food stress, that should be taken seriously.

Ospreys are also one of conservation's great success stories. After suffering dramatic declines in the twentieth century, they recovered because people recognized a problem and acted. It would be tragic to watch that progress erode because we failed to respond to a new threat when warning signs were already visible.

As someone who has spent much of my life photographing and appreciating birds and wildlife, I want future generations to have the same opportunity to watch an Osprey plunge into the water, rise with a fish, and carry it back to a waiting chick. Those moments are part of the natural character of our coast, but they depend on a functioning food web.

I therefore strongly support a 50% reduction in the Chesapeake Bay menhaden fishery cap. Taking a precautionary approach now is far better than waiting until Osprey populations experience a much more serious decline.

Please ensure that enough menhaden remain in the ecosystem to support the Ospreys and other wildlife that depend on them.

Thank you for considering my comments and for your work to protect both sustainable fisheries and healthy coastal ecosystems.

Sincerely,
Tom Cuchara

Dear Members of the Atlantic States Marine Fisheries Commission,

I am writing to urge you to reduce the Chesapeake Bay menhaden fishery cap by 50%.

Ospreys are extraordinarily important to me, both as a nature photographer and as someone who deeply values birds, wildlife, and healthy ecosystems. I have spent countless hours observing and photographing Ospreys, and that time has only strengthened my appreciation for how remarkable they are. Watching an Osprey hover, plunge into the water, emerge with a fish, and return to its nest is not simply a photographic opportunity. It is a reminder of how closely the survival of wildlife is tied to the health of our waterways and food webs.

Ospreys are also important because they function as a sentinel species. Their breeding success can provide an early warning that something is changing in the aquatic environment. Because their diet is overwhelmingly composed of fish, declines in prey availability can quickly translate into failed nests, hungry chicks, and reduced reproductive success.

The recent numbers from Connecticut are deeply concerning. By August 1, 2025, 113 of 706 monitored nests had failed, approximately one in six. During the same period this year, 171 of 691 nests had failed, roughly one in four. The situation at Great Island in Old Lyme is even more alarming. Thirty-seven chicks fledged there in 2024, 27 in 2025, and only five this year.

Those numbers should command our attention.

Atlantic menhaden are not simply a commercial resource. They are a critical forage fish supporting Ospreys and many other species throughout the coastal ecosystem. Management decisions therefore need to consider not only how many menhaden can be harvested, but how many must remain in the ecosystem to sustain the wildlife that depends upon them.

We have seen before what happens when Ospreys warn us that an ecosystem is under stress. Their historic decline helped draw attention to the devastating ecological effects of contaminants such as DDT. Their recovery became one of conservation's great success stories. We should not ignore another warning simply because the cause may now be different.

As a photographer, I value the opportunity to document these magnificent birds, but this issue reaches far beyond photography.

Ospreys are part of Connecticut's natural heritage. They are predators, indicators of ecosystem health, and a visible connection between our waterways, fish populations, and coastal wildlife.

I recognize that fisheries management requires balancing ecological, economic, and commercial interests. But when nest failures are rising so dramatically and a formerly productive Osprey stronghold has fallen from 37 fledged chicks to only five in two years, precaution is warranted.

Please support a 50% reduction in the Chesapeake Bay menhaden fishery cap and ensure that enough forage fish remain in the ecosystem to support Ospreys and the many other animals that depend on them.

Protecting menhaden is not about protecting one bird species alone. It is about protecting an interconnected coastal ecosystem.

Thank you for considering my comments and for your work on behalf of sustainable fisheries and healthy coastal environments.

Sincerely,
Lisa Cuchara, PhD

Please support the reduction of the menhaden fishery cap by 50%. This fish is the main diet of Osprey and just when we saw their numbers thriving after the DDT ban, their numbers are decreasing again due largely in part to their food availability being limited because of overfishing. According to Connecticut Audubon, “Last year, Connecticut Audubon’s Osprey Nation recorded its lowest breeding success since the statewide community science program launched in 2014 to monitor the birds. By Aug. 1, 2025, out of 706 nests with up-to-date reports, 113 had failed — about 1 in 6. In the same timeframe this year, of 691 nests with up-to-date reports, 171 have failed — roughly 1 in 4.“ Menhaden fisheries should be limited to a 50% decrease so that Osprey and other wildlife who use this fish a main food source can continue to thrive.

Public Comment in Support of Reducing the Chesapeake Bay Menhaden Reduction Fishery Cap

To the Atlantic Menhaden Management Board,

I am writing in support of a meaningful reduction to the Chesapeake Bay menhaden reduction fishery cap, including consideration of the full 50% reduction proposed in Draft Addendum II.

Menhaden are much more than a single commercial fishery. They are a critical forage species that supports striped bass, bluefish, weakfish, cobia, red drum, tuna, marine mammals, seabirds, and many other species. Protecting adequate menhaden abundance in the Chesapeake Bay can therefore have benefits that extend well beyond the Bay itself.

This issue also has an important economic component. Recreational and charter fishing supports thousands of small businesses along the Atlantic Coast. Bait and tackle shops, charter captains, marinas, boat dealers, marine mechanics, fuel docks, restaurants, hotels, and coastal tourism businesses all benefit when anglers have healthy fisheries to pursue.

These businesses are spread throughout coastal communities from the Chesapeake Bay to New England and the Southeast. When forage fish such as menhaden are abundant, predators have access to an important food source and anglers have greater opportunities to encounter those predators. Those fishing opportunities translate directly into people buying tackle, booking charter trips, purchasing fuel, maintaining boats, paying marina fees, traveling, eating at local restaurants, and supporting other small businesses.

The Chesapeake Bay is also an important nursery and feeding area. Management should recognize that the value of menhaden cannot be measured solely by the amount that can be harvested and processed. Menhaden left in the ecosystem have value as forage and can contribute to recreational fisheries and coastal economies far beyond where those fish originated.

I therefore support reducing the Chesapeake Bay reduction fishery cap by 50% and establishing quota periods that distribute harvest more evenly throughout the fishing season. Spreading harvest throughout the season could help address concerns about concentrated fishing effort while a lower cap would provide an additional precaution against localized depletion.

This is not about eliminating commercial fishing. It is about balancing the needs of one fishery with the ecological and economic importance of menhaden to the entire Atlantic Coast.

A healthy menhaden population supports healthy predator populations, recreational fishing opportunities, and the countless small businesses and coastal communities that depend on them.

I respectfully ask the Atlantic Menhaden Management Board to adopt strong conservation measures under Draft Addendum II and reduce the Chesapeake Bay reduction fishery cap by 50%.

Thank you for considering my comments and for your continued work managing Atlantic menhaden for the benefit of the entire ecosystem and all stakeholders who depend on it.
-Derek Kettig

Connecticut Audubon is urging the commission to reduce the fishery cap by 50% to help ensure enough menhaden remain available for Ospreys and other wildlife. I am deeply concerned about the dwindling Osprey population in Connecticut. In the current political climate support programs to enable populations of birds and all species to remain stable have been drastically cut. This is wrong. I join my voice with the Audubon Society in asking you to support the Osprey population by capping the fishery numbers for menhaden by 50%. Thank you. Rosemary Tindall-Gibson

I do not support the reduction of the bay quota for menhaden. We have had an abundance of young fish since early March. I fish on the bay daily and see schools of smaller fish everywhere. Those will be next year's harvest size fish.

I would like to add that the menhaden fleet should face financial penalties for bycatch mortality of game fish species. Too many times have I witnessed the blue boats hitting schools of bunker the same say or day after we were catching Spanish, cobia, stripers, drum, etc feeding on these schools. They without a doubt are killing large numbers of “illegal” fish that a recreational angler would be severely punished for.

I enthusiastically support the 50% bay cap and use of quota periods. This travesty has been going on for far too long while we do study after study after study. It's long past time for this body to show some backbone and authority to take a major step to save our bay. Common sense over the past 40-50 years illustrates how destructive this fishery has been to the Chesapeake. Discards and spills due to net tears also need to apply towards the quotas.

Ive been an osprey steward for several years in Old Saybrook, Ct. This year was particularly heartwrenching and devastating, as I watched all 3 healthy appearing offspring die of starvation. Neither parent brought enough Menhaden bait fish to make survival possible. Local fishermen have bemoaned the lack of bait fish. Commercial fishing of these vital fish desperately need regulation. If the decision to do years of research before legislating restrictions occur, Im fearful that worsening the already widespread starvation will result. Please, act quickly!

The research and up to date status of this free for all on the Atlantic Menhaden fish is a terrible idea. Raptors including Osprey and Eagles have begun their resurgence after the poisons of the past. Now the committee wants to cut food from them? Honestly, is there more pressing issues that need addressing other than a food supply being compromised. I believe in the research and data the Ct Audoban releases. Please reconsider this terrible idea.

Please reduce the fishery cap by 50% to help ensure enough menhaden remain available for Ospreys and other wildlife. Our selfishness of always taking more from this earth and robbing from those with no voice must be considered. There is clear evidence that we are killing off this species. The decline at Old Lyme's Great Island, once a former Osprey stronghold, has been particularly severe. Thirty-seven Osprey chicks fledged at Great Island in 2024. In 2025, that number decreased to 27. This year, only five chicks fledged. Because Ospreys feed almost exclusively on fish, the Osprey Nation community science program serves as an early-warning system for the health of Connecticut's waters and the abundance of prey species like Atlantic menhaden.

As a Connecticut shoreline resident for over 15 years, Osprey have been living alongside us as an glowing example of what wildlife conservation and environmental preservation can be. Now, given their alarming recent population declines in recent years, they are also reminder of how fleeting and tenuous those success stories can be if we, the stewards of their habitat, don't remain vigilant. These declines are real and I urge you safeguard and properly manage their food supply to ensure a balanced ecosystem where wildlife and people thrive in harmony. I am neither a fishing expert nor a wildlife expert, but you don't have to be either to observe harmful industry practices with outsized impacts. Please, consider the Osprey as a symbol of the health of Connecticut and beyond and protect their future through sustainable fishing policies. Thank you. Stephen Marsi

WE MUST SAVE THESE MAGNIFICENT OSPREY!! We brought them back from near extinction from the DDT scourge - we cannot let them die from hunger now. When we banned DDT, cleaned up the water, built raised platforms for their nests, they rebounded. The menhaden are their primary food source, but the Chesapeake over-fishing is preventing millions of the fish from reaching CT. I believe that Virginia is the only Eastern state that still allows purse seine net fishing, which captures monstrous amounts of these fish, all for cat and dog food ??? Please, please, please PUT A CAP on the amount of menhaden that can be caught in the Chesapeake. These majestic osprey are starving. Sincerely, Sydney Anderson Old Saybrook, CT

While I recognize the importance of the menhaden fishing industry and the uses of these products, I strongly advocate the implementation of a 50% reduction in the annual fishing quota. There is substantial information indicating a decline in the fish population. for the stability of the industry and to balance concerns for the osprey and other wildlife groups that depend on this fish for food, a quota reduction is required.

I strongly support the reduction of the menhaden fishing cap by the highest possible amount. The research we're seeing about population decline among Osprey in the Chesapeake Bay watershed is staggering. From this article: https://www.audubon.org/magazine/ospreys-chesapeake-bay-are-starving-death-disastrous-rates-what-will-it-take-save-them "[Su]rveying 1,025 nests [...] [t]hey found that Ospreys throughout the main stem of the Bay were producing less than half of the young required for the population to survive—a reproductive rate even lower than during the height of DDT." "[T]he number of menhaden that Ospreys bring to their chicks, CCB data show, has dropped by 80 percent over the past 40 years. " "Virginia-based Ocean Harvesters [...] was permitted to harvest approximately 350 million pounds of menhaden annually, including 110 million pounds from the Chesapeake. This amounts to roughly 70 percent of the catch for the entire Atlantic menhaden population." "Two years earlier, Colonial Beach had 55 successful fledglings from 35 nests. That summer they had 8 fledglings. " And in New Jersey: "There were 40 nests in the immediate area, all historically successful. The year before, they had produced 55 young. I asked how many had been successful this past year. 'Five,' Wurst said." The impact of overfishing of menhaden is undeniable. While other factors, including climate change, surely contribute to the overall population decline of that species, it is our responsibility to respond and adapt to that decline to ensure the sustainability of the species AND the industries they support. "A 2025 report from the Potomac River Fisheries Commission found that menhaden landings for bait fishermen were one-third of the all-time low, set just two years before." Urgent action is needed. Osprey populations will continue to starve without it; an ignoble end for a magnificent species. Humans have taken collective action to save this beautiful bird once before, and we can do so again.

I am a Virginia resident and recreational angler who spends substantial time on the Chesapeake Bay and its tributaries. I strongly support reducing Atlantic menhaden harvest and substantially reducing—and ultimately eliminating—the industrial reduction fishery within the Chesapeake Bay.

Menhaden are not simply another harvested species. They are a foundational forage fish in the Chesapeake ecosystem, supporting striped bass, bluefish, weakfish, other predatory fish, marine mammals, and birds. Management should therefore consider not only whether the coastwide menhaden stock meets a conventional overfished/overfishing threshold, but whether enough menhaden remain available where and when Chesapeake Bay predators need them.

The Draft Addendum notes that more than half of the Bay reduction landings in 2023 and 2024 were taken during a six-week period in midsummer and acknowledges that concentrated removals may affect menhaden availability to other fisheries and predators. It also documents substantial declines in Chesapeake Bay pound-net catches and CPUE in 2024, as well as a dramatic decline in the Maryland DNR Choptank River adult menhaden index in 2024 that remained low in 2025. These observations do not prove that reduction fishing is the sole cause of reduced local availability, but they are precisely the kind of warning signals for which precautionary management is appropriate.

There is also increasingly concerning ecological evidence. A large 2026 study of Chesapeake Bay ospreys found widespread reproductive deficits and evidence of food stress in higher-salinity portions of the Bay, with the authors identifying reduced availability of Atlantic menhaden as a likely primary driver of poor reproductive performance in those areas.

For Draft Addendum II specifically, I support the maximum reduction presently available under Section 3.1: Option B4, a 50% reduction of the Chesapeake Bay Reduction Fishery Cap to 25,500 metric tons. I prefer B4 to a mechanism that could automatically increase the Bay Cap again if the coastwide TAC rises in the future. If the Board instead chooses to link the Bay Cap to the coastwide TAC under Option C, I support C1e, the lowest proposed proportion at 13.6%, paired with C2a so that there is no lower floor preventing additional reductions when the coastwide TAC declines.

We all love wildlife. Menhadin is the bait fish that drives he health of our ecosystem. It is imperative that this resource not be overfished to the point where it is detrimental to other stake holders. Please do the responsible thing as stewards of the environment and set catch levels 50% lower than what is being proposed. Thank you.

I am writing to urge the Atlantic States Marine Fisheries Commission to PLACE A 50% REDUCTION in menhaden catches in the Chesapeake Bay. This step is necessary to protect the ospreys along the seaboard. I live in Connecticut and as a birder, enjoy that ospreys are a common sight. They thrived along our coast after DDT was eliminated and their presence is often touted as proof that Long Island Sound is healthy. However, this year I noticed a decline in nests in locations - fewer nests and/or fewer chicks - where previously there were several successful ones. Data emerging from CT Audubon Society have confirmed that across our state ospreys are raising fewer chicks and more are starving. Menhaden serve as a primary source of food for the ospreys throughout the region. Over-fishing by commercial fleets has adversely impacted the number of fish leading to this sudden and precipitous decline in osprey numbers. Just as with the DDT threat to the osprey's survival, humans caused the problem and we can solve it. Ospreys are telling us that we are taking too much from the sea. The greed of commercial companies should not control the fate of these magnificent birds. We must give them a chance by doing all we can to protect their environment, starting with protecting their primary food source. TAKE ACTION NOW - REDUCE THE CATCH BY 50%!

Hello! It was very disheartening to learn about the decrease in fledged Ospreys in the past few years. I wholeheartedly hope that you will support lowering the fishing cap so that there are enough fish for everyone, including the birds!! Thank you!

I am totally in favor of reducing the fishery cap for menhaden in the Chesapeake Bay by 50%. Osprey were nearly wiped out before by the use of DDT. Now, we are introducing a new hazard that will be detrimental to their survival by eliminating their food source.

I live in Easton Ct and observe the activities of Osprey off Fairfield Bridgeport, Stratford & Milford CT. I am a regular kayaker boater & beach goer. What I have been observing is the increased amount of time and distance it takes the birds to find and catch the bunker (maidenhair) this year. It is significantly longer than past years. It's also sad that the bluefish are disappearing from Long Island Sound, persuadably from the lack of food (bunker). I trust you will strongly consider the reduction of commercial fishing to "balance" the food sources for our native fish, birds & other animals. Sincerely, Doug Williams

Biodiversity is not merely this planet's greatest treasure, but also the bedrock supporting survival and vitality for all interconnected species, humans included. The case might be made that Ospreys are no less deserving of their food supply than are we- but we need not be so selfless. Taking a selfish position: our failure to share the resources of this planet with other species puts our own at risk by disrupting entire ecosystems, a phenomenon we see playing out all around the world. We teach our children the virtues of sharing- and we are right to do so. Will we not heed our own lessons? I speak for the Ospreys, who cannot speak for themselves. And I speak for us, too- for they, and we, are both part of something bigger than any one species. Life itself is a gift we share; the sustenance of life must be shared as well. Thank you- David L. Katz, MD, MPH; CT resident, parent

The status of Osprey in Connecticut is alarming. We have monitored nests for 12 years and last year, 3025, and this year show a huge decline in successful hatchlings. To further imperil these and other wildfowl by allowing commercial fishers to take a larger number of fish, would be a crime against wildlife, which is already struggling to live. Think about a world without Osprey swirling on the updrafts; our children and grandchildren would never see those free flying magnificent birds. That would be so sad. Thank you, Anne Kugielsky

Menhaden have a critical place in the food chain that supports birds and fish along the coats from the Mid-Atlantic to New England. Thus this should be recognized by the NOAA scientists and appropriately protected if the goal is to maintain the balance in species that rely upon this food source. As a citizen who spends a lot of money on recreational activities associated with the coast I feel that the total recreational $s invested far outweigh the commercial impact on the economy.

We support limiting the fishing of “bunkers” to 50 percent of what is being done now as a first step. We do not want the same fate as the cod. Bunkers are needed in the food chain for blues, striped bass, osprey, etc. We also support no use of drones for offshore fishing. Also support no wide net dragging/fishing. Suggest to fisher folks they invent a replacement for the bunker! Thank you Martha Staniford

Public Comment in Strong Support of a 50% Chesapeake Bay Cap Reduction and Seasonal Quota Distribution in Draft Addendum II to Amendment 3

Commenter: Jeremy Schreifels, PhD

I am writing in strong support of the most protective measures under consideration in Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden. I urge the Atlantic Menhaden Management Board to cut the Chesapeake Bay reduction-fishery cap by 50% and to spread that harvest across the season with seasonal quota periods.

I also urge the Board to go further: require real monitoring and public reporting of the reduction fishery, restrict purse-seine fishing in sensitive areas and at sensitive times, and limit the use of spotter aircraft that help the fleet find and empty out schools of fish.

As a homeowner on the Severn River, I've watched the Bay's fish and bird life change from my own backyard. My observations aren't a substitute for scientific monitoring, but they line up with a growing body of research documenting real food-web and reproductive problems in parts of the Chesapeake Bay.

Requested management actions
I respectfully ask the Atlantic Menhaden Management Board to adopt the following:

1. Cut the Chesapeake Bay cap by 50%
Reduce the current 51,000-metric-ton cap to 25,500 metric tons a year (or lower). This is the most protective option in Draft Addendum II, and it's the level ASMFC's own 2025 assessment says is needed to meaningfully reduce the odds that fishing mortality stays too high. [1, 2]

2. Split the cap into three seasonal quota periods
Spread the reduced cap across three periods so the fleet can't take it all in one spring-and-summer push — exactly when Bay predators need menhaden most. This option is already on the table in Draft Addendum II and directly addresses ASMFC's own concern about concentrated fishing effort. [1]

3. Require real electronic monitoring and public reporting
Every reduction-fishery vessel operating in the Bay should report electronically, not just through weekly landings totals. At minimum, the system should include:
- electronic, trip-level reporting of catch, effort, date, time, location, and vessel identification for every landing in the Bay
- vessel monitoring systems (VMS) or equivalent electronic location tracking on all reduction-fishery vessels
- real-time or near-real-time quota accounting as the Bay cap is approached, with automatic closure before it's exceeded
- independent auditing of landings and compliance
- public reporting, both ongoing aggregate data and a public annual report on compliance, quota use, fishing locations, effort, and bycatch

The 2019 cap violation, discussed below, shows why this matters: a cap nobody can verify in real time isn't a real limit.

4. Add stronger time and area protections
Establish closures or other protections for menhaden during critical periods and in areas important for spawning, nursery habitat, and predator feeding. This is consistent with the precautionary options the Chesapeake Bay Work Group has already considered. [3]

5. Restrict purse-seine fishing in ecologically sensitive areas
Limit purse-seine operations in tributaries and other areas where concentrated harvest could strip a local area of menhaden or interfere with predators feeding there.

6. Restrict or prohibit spotter aircraft and drones in the Bay
Spotter planes and drones make it far easier for the fleet to find and quickly harvest concentrated schools of fish. That capability deserves real limits inside a confined system like the Chesapeake Bay.

7. Improve location-specific monitoring and assessment
Fund and require better data on menhaden abundance, catch, effort, and predator interactions at the Bay and tributary scale. ASMFC already identifies better fine-scale data and models as a research priority. [1]

Why these measures are needed
Based on the scientific literature, ASMFC's analyses, and what I've observed, the following evidence supports my requested management actions:

1. Menhaden are a key foundation for the Chesapeake Bay food web

Atlantic menhaden aren't just another commercially caught fish, they're a forage species, meaning much of what they eat gets passed up the food chain when bigger fish, birds, and other predators eat them. NOAA Fisheries describes menhaden as an important prey species and highlights their role in the Chesapeake Bay ecosystem. [1]
Menhaden also link the Atlantic Ocean to the Bay through their life cycle: they spawn offshore, their larvae drift into estuaries like the Chesapeake to grow up, and the juveniles eventually head back out to coastal waters. [1] The Bay has long been an important nursery for menhaden, and research shows it contributes substantially to the coastwide population. [2, 3]

Because menhaden are such important prey here, removing large numbers from one area of the Bay during the season when predators depend on them has consequences that go well beyond the fish that were caught.

2. Menhaden abundance has remained low compared with historical levels

The long-term record backs up the case for greater caution. A peer-reviewed analysis of six decades of Atlantic menhaden data found that abundance remains well below the highs of the 1970s and '80s, and that recruitment (i.e., the number of young fish surviving to join the population) has stayed unusually low in the Bay. The study flagged that persistent low recruitment as a real concern for managers trying to sustain both the fishery and menhaden's role as forage for other species. [4]

3. The osprey population is suffering

Recent research led by Bryan Watts and colleagues at the Center for Conservation Biology at William & Mary, working with the U.S. Geological Survey and other institutions, provides strong evidence of widespread reproductive problems in Chesapeake Bay ospreys.

A 2026 peer-reviewed study monitored 571 osprey nests across the Bay during the 2024 breeding season. Nests in high-salinity areas produced far fewer surviving young than nests in low-salinity areas. The produced so few, in fact, that every high-salinity area studied was losing ospreys faster than it was producing them, while low-salinity areas were producing a surplus. The researchers concluded that reduced menhaden availability is a primary driver of the poor reproduction in high-salinity waters. [5]

Earlier research in the lower Bay documented a long-term decline in how much food ospreys were bringing to their nests and in their reproductive success, tied to swings in menhaden availability. [6] The long-term numbers are troubling: in Mobjack Bay, the rate at which menhaden were delivered to osprey nests dropped by more than 80% over the study period. Because menhaden

are unusually calorie-dense compared to other fish, that shift cut the overall energy value of the osprey diet by roughly half. [6]

We're seeing reduced food availability and reproductive failure right now, in a highly visible, fish-dependent predator. I've tracked osprey nests along the Severn River near my home. In 2024, two of four monitored nests failed. In 2025, two of three failed. In 2026, only two pairs returned to these sites. I know this is a small sample that can't establish cause on its own. I offer it as a local observation consistent with the much broader scientific evidence of food stress and reproductive problems now being documented across parts of the Bay.

The Commission shouldn't wait until local populations have declined past the point of recovery before acting.

4. A coastwide "healthy" stock does not resolve the problem in the Chesapeake Bay

ASMFC's current assessment doesn't classify Atlantic menhaden as overfished or experiencing overfishing coastwide. [7] But that doesn't answer the question in front of the Board. ASMFC itself acknowledges that its current models can't produce a stock status or harvest advice for a smaller region like the Chesapeake Bay separately from the ocean as a whole. [1]

The real question for the Bay is: is there enough menhaden in the Bay to support the Bay's ecology? ASMFC's own Chesapeake Bay Work Group couldn't answer that question. It still identified changes in menhaden availability, predator needs, and the timing of the Bay fishery as reasons to consider additional precautionary management. [3]
That uncertainty is a strong argument for caution, not for leaning on a coastwide average that wasn't designed to answer this question.

5. The 2019 cap violation demonstrates the need for stronger monitoring and enforcement

The history of the Bay cap itself shows why stronger monitoring and public reporting matter. ASMFC established the current 51,000-metric-ton Chesapeake Bay reduction-fishery cap under Amendment 3 in 2017. [1] Virginia hadn't yet written the new cap into its own regulations when, in September 2019, Omega Protein notified ASMFC that it intended to exceed it. ASMFC records show Virginia had been monitoring landings and had already told Omega Protein to stay under the cap. [8]

Omega Protein exceeded it anyway. At its October 2019 meeting, the ASMFC Atlantic Menhaden Management Board reported that the reduction fishery had blown past the 51,000-metric-ton cap on September 6, with Bay landings about 27% over the limit (reaching roughly 65,000 metric tons). [8]

This episode matters for two reasons. First, a cap nobody is actually watching isn't much of a conservation measure. Second, the public still has very little access to the location and operational data needed to independently check how the reduction fishery is affecting the Bay.

ASMFC reports that it currently relies on state and federal partners for monitoring and that Bay landings are reported weekly. [1] Weekly landing totals are a poor substitute for the real electronic monitoring described above.

6. ASMFC's Ecological Reference Points (ERPs) support a substantial reduction

There's another reason to support a 50% reduction: it's what ASMFC's own numbers point to. The Commission's 2025 assessment found that Atlantic menhaden fishing mortality was above the Ecological Reference Point (ERP) target and that fecundity (i.e., the population's egg-producing capacity) was below its ERP target. [9]

In response, the Board cut the 2026 coastwide Total Allowable Catch from 233,550 metric tons to 186,840 metric tons, a 20% reduction. That gets fishing mortality to a zero percent chance of exceeding the ERP threshold, but it still leaves a 100% chance that fishing mortality stays somewhere between the ERP target and the threshold, rather than getting back down to the target itself. [2, 9] Most importantly, ASMFC's own analysis states plainly: "[t]o have a lower probability of being at or above the ERP F target, a 50% or more reduction in the TAC would be required." [2]

A 50% reduction isn't an arbitrary ask. It's the number ASMFC's own technical analysis says is needed to meaningfully reduce the odds that fishing mortality stays at or above a target the stock is not currently meeting.

7. Concentrated harvest is a different problem from coastwide harvest

Fishing pressure isn't spread evenly across a species' range, and its effects aren't either. The Chesapeake Bay cap exists in the first place because of concerns about localized depletion. ASMFC set the original cap in 2006 as a precaution against exactly that. [1] Draft Addendum II raises the same concern again: the Board is looking at cutting the cap by up to 50% and spreading it across three quota periods because reduction-fishery effort has been concentrating in spring and summer, with knock-on effects for other fisheries and the ecosystem. [1]

A school of menhaden pulled out of one tributary isn't available to the osprey, striped bass, or bluefish hunting in that tributary just because plenty of menhaden exist somewhere else, hundreds of miles away. Menhaden's value to the ecosystem depends on where and when they are, not just how many exist coastwide.

Spring and summer matter more than other seasons for this reason. That's when fish and birds need extra energy for growth, migration, breeding, and raising young. Osprey research shows what happens when enough high-energy forage isn't there during the breeding season. [5-6, 11] A single annual quota gives the fleet every incentive to harvest heavily whenever menhaden are most concentrated and easiest to catch, which is often exactly when localized depletion does the most ecological damage. Splitting the cap across three periods spreads that pressure out over the year, so predators aren't left short during the months they need menhaden most.

That's why I support both the 50% cap reduction and the seasonal quota periods.

8. Purse-seine fishing creates additional ecosystem concerns

The Board should also weigh how menhaden are caught, not just how many. Purse seines are extremely efficient at capturing schooling fish, and when paired with spotter aircraft that can locate schools from the air, they let a fleet remove large quantities of fish very quickly from a small area. I'm not arguing purse seines are inherently wrong for catching menhaden, I'm arguing that using them in a confined, ecologically complex estuary like the Chesapeake Bay calls for more caution than using them far offshore.

9. Environmental conditions can concentrate fishing effort

How environmental conditions interact with purse-seine fishing also matters. Langseth and colleagues studied the Gulf menhaden fishery and found that as dissolved oxygen dropped, both menhaden and the fishing fleet shifted toward particular areas, changing where fish could be caught and how easily. [12]

Environmental conditions can change where menhaden gather and where fishing effort follows them. The Bay already sees real variation in oxygen levels, salinity, and temperature across its waters and through the year. Combine that with highly efficient fishing gear, and it's worth watching closely where and when industrial harvest is actually happening.

10. Spotter aircraft and drones should be addressed

I also urge ASMFC and the states to look at restricting spotter aircraft and drones in the Bay. Aircraft dramatically improve the reduction fleet's ability to find dense schools of menhaden, and in a confined system like the Chesapeake, that makes rapid, highly localized removal much easier. Restricting or banning aircraft-assisted purse-seine fishing in the Bay would blunt the fleet's ability to quickly find and empty out isolated concentrations of fish. It also fits the same precautionary logic that led ASMFC to set the Bay cap in the first place.

11. The Commission has already recognized the need for precaution

The strongest argument for precaution is that the Commission has already recognized the problem itself. The Bay cap exists because of concerns about localized depletion. [1] In 2024, ASMFC responded to concerns about menhaden fishing's effects on ospreys by asking USGS scientists for data on osprey abundance, distribution, and diet, and then formed a Work Group to evaluate precautionary options. [3] That Work Group went on to consider time and area restrictions meant to protect fish-eating birds and fish during critical parts of their life cycles. [3] Draft Addendum II now proposes cutting the Bay cap by up to 50% and spreading it across quota periods. [1]

None of this means the Commission has failed to see the problem. It means the opposite: the Commission recognizes that current management may not adequately protect against localized harm. The right response is to act on that recognition.

Conclusion

None of this depends on claiming the entire Atlantic menhaden population is collapsing, or that menhaden are endangered. The case is narrower than that. Menhaden are a foundational forage species, the Chesapeake Bay is one of their most important nurseries, and multiple independent lines of evidence, including juvenile abundance, osprey reproduction, ASMFC's own uncertainty about Bay-specific stock status, the 2019 cap violation, and the Commission's own ERP analysis, all point the same direction.

The question in front of the Board isn't whether we can prove continued harvest will cause ecological collapse. It's whether we have enough information to justify continuing to remove large quantities of a foundational forage species from a confined, ecologically important estuary, when the Commission itself acknowledges real uncertainty about the Bay's local stock status and ecological needs. The short and clear answer is: we don't.

The cost of precaution is a smaller industrial harvest. The cost of not being precautious could be a depleted forage base, struggling predator populations, and a Chesapeake Bay food web in worse shape than the one we have now. I urge the Board to choose precaution:
- cut the Bay cap by 50%
- spread it across three seasonal quota periods
- require real monitoring and public reporting
- move forward on the additional time, area, and gear restrictions described above.

Please add my voice to those requesting a lower limit for catching menhaden. It has been brutal and heart wrenching to watch the osprey nestlings starve to death in their nests for lack of food. Thank you.

Comment

Dear Chair and members of the Atlantic Menhaden Management Board,

My name is Eve Burhenne, and I live in Fairfield, Connecticut, on Long Island Sound, where a healthy Osprey population is one of the clearest signs of a healthy Sound. I'm writing to urge the Board to adopt the strongest option in Draft Addendum II and reduce the Chesapeake Bay Reduction Fishery Cap by 50%.

The evidence is no longer ambiguous. Center for Conservation Biology researchers found that in 2025, Ospreys nesting in the Bay's higher-salinity waters — where they depend most heavily on menhaden — produced only about 0.33 young per pair, far short of the 0.8–1.3 needed just to hold the population steady. Seventy-four percent of the 741 pairs studied there raised no young at all. When researchers hand-fed chicks in failing nests, those chicks thrived while unsupplemented nests kept collapsing — direct evidence that food scarcity, not weather or disease, is driving the decline. Meanwhile, the current Bay Cap — set in 2018 under Amendment 3 — still allows up to 51,000 metric tons of menhaden to be removed from the Bay annually, concentrated in the very months Ospreys are raising young. Draft Addendum II's own Option E, cutting that cap to 25,500 metric tons, is described by ASMFC's Technical Committee as the option that provides "the most conservative buffer" for menhaden and the wildlife that depend on them.

Menhaden anchor the food web for Ospreys, striped bass, and much of what makes Atlantic coastal fisheries and wildlife possible. Modest cuts have not been enough to reverse this decline. Please don't wait for Osprey populations to collapse the way striped bass once did — adopt the 50% cap reduction now, while it can still make a difference.

Thank you for considering my comment.

Sincerely, Eve Burhenne Fairfield, CT

As a native of the Connecticut coast, I consider ospreys an iconic aspect of coastal wildlife. I am deeply concerned that fishing in the Chesapeake Bay is directly contributing to osprey population decline, which also symbolizes disruptions throughout the ecosystem. I encourage the commission to consider these concerns and reduce the menhaden fishing cap by 50% per the CT Audubon Society's recommendation.

In October 2025, the Atlantic Menhaden Management Board (Board) initiated Draft Addendum II, which will consider reducing the Chesapeake Bay reduction fishery cap by up to 50% and creating quota periods to distribute harvest under the cap more evenly throughout the fishing season. The Draft Addendum responds to concerns about a concentration of effort that may be affecting other fisheries within the Bay and other potential ecological impacts. I support this Draft Addendum II to save the osprey. A quota is essential. Please pass this!

If they continue to overfish the menhaden there won't be any fish left in the bay. It is a keystone species which supports the ecosystem of the Chesapeake bay and the repercussions of this over fishing are already occurring. The osprey nestings failed this summer the chicks starved in the nest. Bald eagles are also dependent on this food source, as are the terns, seagulls and waterfowl. A fifty percent reduction at least, might lead to a more balanced environmental impact.

Comment

I strongly support meaningful reductions to the Chesapeake Bay menhaden reduction fishery cap and support the most precautionary management measures available under Draft Addendum II.

As a recreational angler and someone who cares deeply about the long-term health of our Mid-Atlantic fisheries, I have become increasingly concerned about the concentration of large-scale menhaden harvests in the Chesapeake Bay and surrounding waters. Menhaden are one of the most important forage species on the Atlantic Coast and serve as a critical food source for striped bass, bluefish, weakfish, osprey, dolphins, whales, and many other predators. The health of these species is directly connected to the availability of menhaden in local ecosystems.

The ASMFC has acknowledged concerns that concentrated harvest effort may be affecting other fisheries in the Bay and causing broader ecological impacts. Draft Addendum II was initiated specifically to evaluate reductions in the Chesapeake Bay reduction fishery cap by up to 50% and to distribute harvest more evenly throughout the season. These measures are intended to address concerns about concentrated fishing effort and ecosystem impacts.

From New Jersey to Maryland, many anglers, charter operators, and coastal communities have observed fewer bait schools,

changing predator behavior, and localized impacts that raise legitimate concerns about the current management approach. While stock-wide assessments may indicate the species is not overfished, localized depletion remains a serious concern when such an ecologically important forage fish is removed in large quantities from a relatively concentrated area.

I urge the Commission to adopt a significant reduction in the Chesapeake Bay cap, preferably the maximum reduction under consideration, and implement seasonal quota periods that prevent excessive harvest during key feeding and spawning periods. Taking precautionary action now is a responsible step that will help protect biodiversity, strengthen the forage base for recreationally and commercially valuable species, and support the long-term resilience of the Atlantic marine ecosystem.

Menhaden are far more valuable in the water as a forage species supporting healthy fisheries, wildlife, and coastal economies than they are as an industrial reduction fishery commodity. I respectfully ask the Board to prioritize ecosystem health and adopt the strongest conservation measures available in Draft Addendum II.

Thank you for your consideration.

There are no menhaden schools left in Long Island Sound. This is a direct result of the commercial fishing being done in the Chesapeake. Species are starving and this has created an unsustainable scenario for the wellbeing of the ecosystem. Do the right thing, and recommend a halt on the overfishing of this fish which feeds so many species.

To the Atlantic States Marine Fisheries Commission: ATLANTIC MENHADEN DRAFT ADDENDUM II

I am writing to strongly urge the Atlantic States Marine Fisheries Commission to adopt the strongest protections being considered under Atlantic Menhaden Draft Addendum II, including the maximum 50% reduction in the Chesapeake Bay menhaden reduction-fishery cap and meaningful seasonal harvest limits.

I live in Northampton County on Virginia's Eastern Shore, just a short walk from the Chesapeake Bay. My husband and I have spent more than twenty years turning our property into a haven for birds and other wildlife, and watching the wildlife of the Chesapeake is one of the great joys of living here. Osprey are an especially treasured part of life on the Bay. Each spring, their return feels like the return of an old friend.

That is why the 2026 findings from the Center for Conservation Biology at William & Mary are so heartbreaking.

Researchers monitored 937 osprey pairs throughout the Chesapeake Bay during the 2026 breeding season and recorded the worst breeding productivity ever documented for Chesapeake Bay osprey.

In waters with salinity above 5 parts per thousand, researchers monitored 769 osprey pairs. They produced an average of only 0.25 young per pair—far below the estimated 0.8 to 1.3 young per pair needed to maintain a stable population.

Even more alarming, 81 percent of those osprey pairs failed to fledge a single young.

This is not an isolated bad year. Productivity in these portions of the Chesapeake has fallen from 0.51 young per pair in 2024, to 0.35 in 2025, and now to just 0.25 in 2026.

These are not abstract statistics to those of us who live on the Chesapeake Bay. Many of my neighbors live directly on the water and have osprey nesting on pilings just offshore from their beaches. I hear them talk about the same heartbreaking thing year after year: the osprey return and occupy their nests, but there are no surviving offspring or fledglings.

Scientists are now documenting what those of us living along the Bay are witnessing firsthand.

The contrast within the Chesapeake is especially troubling. In tidal freshwater areas, 168 monitored osprey pairs produced an average of 1.04 young per pair—above the minimum level required for population maintenance. Yet throughout the saltier waters, where osprey depend much more heavily upon Atlantic menhaden, reproductive success has collapsed.

Researchers have documented unmistakable signs of severe food stress: reduced food delivery to nests, emaciated and underdeveloped chicks, shrinking brood sizes, nest abandonment, and young starving in their nests.

Menhaden may be small fish, but their importance to the Chesapeake ecosystem is enormous. They are a highly nutritious forage fish and an essential food source for osprey, striped bass, and numerous other predators.

When we remove menhaden from the Chesapeake Bay on an industrial scale, we are not simply harvesting one species of fish. We are removing food from an interconnected ecosystem that depends upon them.

I understand that commercial fishing is an industry and that people depend upon it for their livelihoods. But the Chesapeake Bay is not merely a resource to be extracted from. It is an ecosystem that belongs to all of us, and one we have an obligation to protect for future generations.

The appropriate question should not simply be how many menhaden can be harvested without collapsing the menhaden population itself. We must also ask how many menhaden need to remain in the Chesapeake Bay to perform their essential ecological role and sustain the osprey, striped bass, and countless other species that depend upon them.

Scientists have appropriately acknowledged that commercial harvest may not be the only factor affecting menhaden availability. Climate change, changes in distribution, and the timing of menhaden entering the Bay may also contribute. But that uncertainty is not a reason for inaction. It is a reason for precaution.

We cannot control every environmental factor affecting the Chesapeake Bay. We CAN control how many menhaden we remove from it.

For that reason, I strongly support the maximum 50% reduction being considered for the Chesapeake Bay menhaden reduction-fishery cap, along with seasonal quota periods designed to prevent excessive harvest from being concentrated during critical portions of the osprey breeding season.

If we act aggressively now and later discover that we were more cautious than necessary, the Chesapeake ecosystem will have benefited from having more forage fish in its waters. But if we wait until the evidence becomes impossible to ignore, we may discover that we waited too long.

The Chesapeake Bay supports the largest breeding population of osprey in the world. Scientists now estimate that, without improvement in reproductive success, this population could decline by approximately 14 percent per year and by roughly 50 percent over the coming decade.

I do not want a Chesapeake Bay where future generations look at empty nesting platforms and abandoned pilings and hear stories about how plentiful these magnificent birds once were.

Please protect the menhaden that sustain the Chesapeake food web.

Protect the osprey.

Protect the striped bass and the countless other species that depend upon a healthy Bay.

The Chesapeake Bay cannot speak for itself, and neither can the wildlife that depends upon it. Those of us who love this

extraordinary place must speak for them.

Please adopt the strongest protections available under Atlantic Menhaden Draft Addendum II.

Thank you for considering my comments.

Respectfully,

Melissa R. Paeglow

I am writing to request that there be significant reductions in the amount of Menhaden that can caught by commercial fishermen. I have witnessed first hand the impact commercial fishing has had on the osprey population. This year in our marsh there were no osprey that had babes out of the 5 nesting oprey nests. We usually have 2 to 3 osprey babies per nest. Thank you in advance for significantly reducing the amount of Menhaden that can be commercially fished to protect the osprey.

I live at the West end of Hammonasset Beach State Park in Connecticut and have been a monitor for Osprey Nation of CT, and this year was noticeably different. Every morning I walk to our nearby beach at sunrise to photograph birds and watch the osprey fish. This year, the osprey seemed to go out farther into Long Island Sound and often return with no fish or very small fish, not like in the past. It was disconcerting to watch, and my fears that there was a more systemic problem seem to have been borne out by the statistics gathered by the state of Connecticut..As a cardiologist, I have been concerned about the overfishing of Menhaden as a primary source of Omega-3 fatty acids since the 1990's. My fears appear to be justified. There is strong preliminary evidence that a lack of nutrition is the cause.
Please consider a moratorium at some level to stop the critical loss of ospreys before it is too late.
Thank you

Dear ASMFC,
I have been an osprey lover for decades, always watching the skies of the New England coast for osprey, from March to September. I have also been an osprey steward with CT Audubon for 4 years. The evidence we're seeing, with the crash of the osprey population in Chesapeake Bay and New Jersey, and now with the new report from CT Audubon, with the discouraging results of the 2026 osprey season, I am begging you to reduce the amount of menhaden that can be commercially fished along the eastern seaboard.
Given the success of the environmental movement of the 70's, to establish the Clean Water Act and halt the use of DDT as a pesticide, it's been heartening to watch the remarkable comeback of all birds of prey - from the bald eagle, to osprey, to the red tailed hawk. It would be a crime to have that effort be for naught, only to have the osprey taking another hit due to the scarcity of their primary food source. The birds are literally starving to death in their nests. Please do not give in to the lobbying efforts of Omega 3 - please do the right thing and reduce what they can take. They've already taken too much. Thank you in advance for your efforts.

Please take action to protect the ospreys' primary food source, including menhaden. As a precautionary measure, I'm urging the ASMFC to reduce the fishery cap by 50% to ensure that the survival of both menhaden and the osprey are not further jeaopardized.

Comment

To the Atlantic States Marine Fisheries Commission,

I am a committed conservationist and I have a particular focus on ospreys and other bird species. As a member of the Connecticut Audubon Society, I have been an osprey nest monitor for a number of years. Since 2014, the CAS has run the Osprey Nation Program in partnership with CTDEEP. It monitors the size, productivity and health of Connecticut's osprey population. Approximately 450 volunteer stewards monitor nearly 1,000 nests each season. In 2025, the program recorded its lowest breeding success ever. While we are waiting for the final report, it is already evident that this year is even more devastating. (Reports available online and upon request).

Menhaden play a key role in supporting Connecticut's osprey populations and it is becoming apparent that the decline in migrating menhaden populations from the Chesapeake Bay are having an effect on our waters in the Long Island Sound. This year, Connecticut's osprey monitors witnessed first-hand, too many young osprey starving to death because of inadequate supplies of menhaden.

I urge you to take the following decisive action:

Adopt Sub Option B4: a one-time 50% reduction in the bay cap
Adopt Quota Period B2: 25-25-50% allocations to delay seasonal harvests

Thank you for your serious consideration of adjusting the harvest quotas and timing to ensure the sustainability of osprey and other species within the menhaden food chain.

Please save our beautiful Osprey population!
We live on Long Island Sound and have noticed the very low numbers of Osprey diving for fish in the Sound. We have also noticed the absence of menhaden schools being chased by the blues. They just are not there !
Correct this situation by limiting the amount of menhaden fished out of the Chesapeake.

This resource for the Osprey is critical and must be restored.

Thank you

Amid growing concern that Osprey populations along the Eastern seaboard are declining due to a lack of food, I urge the ASMFC to reduce the fishery cap by 50%, a precautionary measure to ensure that menhaden, a key foundation fish and a prime food source for Connecticut's Osprey, are not put in even greater jeopardy.

Even more so now, the numbers show that Osprey and other species that rely on menhaden do not have years longer to wait. This year, Osprey Nation also saw a high number of nest failures and a severe drop in the number of nests that fledged three chicks. Of 679 total nest attempts, 40% failed. Failures include nests where incubation was unsuccessful as well as nests where chicks hatched but did not survive to fledging. Both types of failure can be associated with food stress, although weather, disturbance, predation, inexperience, and other factors can also contribute to unsuccessful nests.

Meanwhile, only 23 nests — less than 6% of all nests — fledged three chicks this year. In previous seasons, up to 20% fell into this category.

Please reduce the fishery cap by 50% to help Connecticut's Osprey!

As a fishing guide/charter captain and recreational boat salesman for over 15 years, I advocate for reducing the mehaden harvest in the Chesapeake Bay by 50%. The Chesapeake Bay is a vital estuary to sustaining many species that many other jobs outside of Omega Protien rely upon, including mine. The localized depletion over the years has resulted on many ill-effects on the abundance of many fish species and wildlife. I cannot think of one species that is thriving or growing in abundance that relies on upon menhaden as a food source in the Chesapeake Bay as a result. This has had effects on many coastal fisheries as well.

I cannot speak to the overall coastal harvest of menhaden but know that the Chesapeake estuary is too vital to the overall health of many other fisheries. Do not tie the Chesapeake to the coastal harvest either. The Chesapeake should alwasys be evaluated seperately and regularly to ensure abundant food sources for all other species are maintained.

ASMFC reports that recreational harvest accounts for only about 1% of Atlantic menhaden landings, meaning that virtually all menhaden harvested are taken by commercial fisheries. Menhaden are a public fishery resource and I believe their management should place greater emphasis on the benefits they provide to the broader public and the marine ecosystem, rather than primarily on their value after commercial harvest.

As a saltwater fisherman, underwater photographer, and biologist, I would like to see more menhaden remain in the ocean. Menhaden are a critical forage species that transfer energy from plankton to larger predators and provide an important food source for species including striped bass, bluefish, tuna, marine mammals, and seabirds. Their value therefore extends far beyond the value of the fish that are commercially harvested.

More abundant menhaden can benefit recreational fisheries, wildlife viewing, marine predators, coastal ecosystems, and the people and businesses that depend on those resources. I would like to see menhaden managed first and foremost for their ecological role as forage and for the broad public benefits that result from healthy and abundant menhaden populations.

A healthy marine food web requires a strong forage base. Menhaden are an important part of that base, and removing them

from the ecosystem has an opportunity cost: every fish harvested for reduction or bait is a fish that is no longer available to support predators and the surrounding ecosystem.

Please manage Atlantic menhaden as the important public resource they are, with greater consideration for the anglers, wildlife, coastal communities, and marine ecosystems that benefit from abundant menhaden, and not primarily for the commercial interests that harvest them for products such as fish meal and fish oil.

Submitted by: The Safina Center, 80 North Country Road, Setauket, NY 11733

Subject: Recommendations for Addendum II to Amendment 3 of the Atlantic Menhaden Fishery Management Plan.
October 3, 2026
To Atlantic Menhaden Management Board:
The crisis of regionwide menhaden collapse requires the most protective measures on every point. We ask the Commission to implement:
(§3.1, Option C1e). 25,500 mt Chesapeake Bay Reduction Fishery Cap, as a fixed 13.6% share of the coastwide TAC.
1. (§3.1, Option C2a). Set an upper limit on the Cap of 51,000 mt with no lower limit;
2. (§3.2.1, Option B2). Split the Cap into 3 seasonal quota periods of even length and uneven take, which reduces catch during critical breeding periods for menhaden-reliant species in the Bay;
3. (§3.2.2, Option B). Implement a quota period overage payback with rollover of unused quota within a fishing year, and ensure that rollovers of unused quota transfer from Quota Period 1 to Quota Period 3 to protect other wildlife that rely on menhaden during their breeding seasons (No to Underage Sub Option 1, §3.2.2);
4. (§3.3, Option B). Revisit the Bay Cap every three years, given the uncertainty of menhaden's status in the Bay and ongoing

work to develop a scientifically realistic Bay Cap.
Commentary: ASMFC's most protective Addendum options remain inadequate. Population models should reflect reality. Your menhaden model has been in a crisis of wildly disparate estimates of natural mortality, while the most visible bioindicator (Osprey) is starving wholesale, and recreational and commercial fishermen in the Mid-Atlantic region report widespread menhaden scarcity or absence. These realities falsify the menhaden population model; your model has been essentially worthless.
Your fundamentally flawed model cannot reasonably justify the obvious, ongoing ASMFC-sanctioned destruction of this keystone species that shapes countless people, fish, and other wildlife throughout our region. The 'most important fish in the sea' is most valuable in the sea of the United States–not sent to Canadian salmon farms.

ASMFC has acute social and legal responsibilities to revise the stock assessments using corrected menhaden natural mortality published by Ault & Luo (2026), and to fully incorporate mammals, birds, and a wider variety of fishes into ecological references, so that menhaden can regain their population strength, rebuild, and re-contribute their historic ecological values.

Sincerely,
Dr. Carl Safina

Dear Atlantic States Marine Fisheries Commission,

My name is Eric Zullo and I am a lifelong angler and member of the Rumson Fair Haven Regional HS Fishing Club in Rumson, NJ. I am writing to express my strong support for the most protective and aggressive conservation options presented in Draft Addendum II to Amendment 3 of the Interstate Fishery Management Plan for Atlantic Menhaden.

As a stakeholder concerned with the health of our coastal ecosystems, I urge the Commission to implement a 50% reduction to the current Chesapeake Bay reduction fishery cap. Menhaden are a vital forage species, and industrial-scale reduction fishing in the Bay severely impacts local ecosystems, depriving critical predators like striped bass and ospreys of their primary food source.
Furthermore, I support establishing strict seasonal quota periods to prevent heavy harvest concentrations during critical summer months, alongside robust periodic review provisions to continuously adapt management based on localized depletion data.

Please prioritize ecosystem-based management and approve the most restrictive options to safeguard the Chesapeake Bay

and our coastwide marine life.

Thank you for your consideration.
Eric Zullo

Comment

Dear Members of the Atlantic States Marine Fisheries Commission (ASMFC):
I am writing as a Maryland resident who has lived in St. Mary's County since 1952, and I have developed a deep personal connection to the Chesapeake Bay. I am an avid sailor, boater, angler and conservationist, and I am someone who spends considerable time on and around the Bay. I am also deeply interested in the wildlife that depends upon this remarkable ecosystem, particularly osprey, striped bass, sharks, whales, and other species whose survival is tied directly or indirectly to a healthy forage base.
I strongly support a 50 percent reduction in the Chesapeake Bay reduction-fishery cap, from 51,000 metric tons to 25,500 metric tons annually. I also strongly support establishing seasonal quota periods for menhaden so that harvest is distributed throughout the year rather than concentrated in an intense summer fishing window.
The Chesapeake Bay is facing an ecological crisis that should not be minimized or postponed. Declining productivity, widespread osprey nest failures, and continued concerns about the condition of the striped bass population are warning signs that demand a precautionary approach to the management of one of the Bay's most important forage fish - menhaden.
Menhaden are not merely another commercial commodity. They are a foundational component of the Chesapeake Bay food web. They provide critical forage for striped bass, osprey, bluefish, weakfish, dolphins, and numerous other predators. Removing very large quantities of menhaden from the Bay during the period when they are most concentrated and most

biologically important deserves particularly careful scrutiny.
The scale and timing of the reduction fishery are especially troubling. More than 100 million pounds of menhaden can be removed under the existing Chesapeake Bay reduction-fishery cap. When that harvest is concentrated into a relatively short summer period, the ecological effect is not simply a matter of the annual tonnage. Where and when the fish are removed matters.
An intense summer harvest can create localized depletion at precisely the time when menhaden are serving as forage for other species. It also potentially deprives recreational anglers, commercial watermen, charter operators, and the broader coastal tourism economy of access to a shared public resource. These competing interests deserve meaningful consideration in the management process.
I am particularly concerned about allowing an annual quota to be treated as though the timing of harvest is irrelevant. It is not. A fish removed from the Bay in June is not ecologically equivalent to that same fish being harvested months later. The Bay's predators have seasonal feeding requirements, and the availability of forage during critical periods can matter greatly to their survival and reproductive success.
For that reason, I urge the Commission to establish strict seasonal quota periods that distribute the allowable harvest more evenly throughout the year and prevent the reduction fishery from concentrating an extraordinary volume of harvest into the summer months. Seasonal management would provide a more precautionary approach and would better recognize the fact that Chesapeake Bay is a dynamic ecosystem rather than simply another geographic allocation within a coastwide fishery.
There is also an important management issue that deserves attention. The Commission's coastwide menhaden assessment does not provide the same level of quantitative information about menhaden abundance and availability specifically within Chesapeake Bay. That uncertainty argues for caution—not for assuming that the Bay can safely sustain the maximum allowable harvest.
The Chesapeake Bay belongs to all of us. It belongs to the watermen who have made their living here, the recreational fishermen who pursue its species, the sailors and boaters who enjoy its waters, the communities whose economies depend upon it, and the wildlife that has no voice in these proceedings. Menhaden management should reflect that broader public interest.
I respectfully urge the Commission to:
1. Reduce the Chesapeake Bay reduction-fishery cap by 50 percent, from 51,000 metric tons to 25,500 metric tons per year.
2. Establish firm seasonal quota periods for menhaden.
3. **Prevent excessive concentration of reduction harvest during the summer months.
4. Apply a precautionary approach in light of ecological uncertainty and the importance of menhaden as forage.
5. Give meaningful consideration to the needs of striped bass, osprey, other predators, recreational anglers, watermen, charter operators, and the Bay's broader tourism economy.
I have spent years watching, enjoying, and caring about the Chesapeake Bay. I have seen firsthand what makes this ecosystem extraordinary, and I am increasingly concerned about the signs that its productivity and resilience are being strained.
We should not wait until the consequences are unmistakable before acting.
The prudent course is to reduce the intensity of the reduction fishery now, protect menhaden as a critical forage resource, and distribute harvest in a manner that gives the Chesapeake Bay ecosystem a better opportunity to sustain the wildlife and fisheries that depend upon it.
Thank you for your consideration and for your responsibility to future generations of Chesapeake Bay users and stewards.
Sincerely,
Lawrence P "Larry" O'Brien
St. Mary's County, Maryland

Menhaden are one of the most important fish on the AtlanticCoast. They are a vital food source for Osprey and other sea-bird species and fish along our shoreline. They are also a key forage fish species that many of our bait-fisheries, coastal communities, and small businesses rely on. The Osprey population has struggled in recent years. Research has shown that a healthy menhaden population is critical to the Osprey's survival as well as the health of the entire Chesapeake Bay.

As a concerned stakeholder, I want to thank you for the opportunity to comment on Draft Addendum II. I support the following management option.

**3.2: Option B2. I support the establishment of three quota periods for the Bay Cap at a 25/25/50% harvest distribution percentage per quota period. This will help reduce food competition for birds like osprey during the most vulnerable times of their life cycles.

Members of the Board,

I support the Board implementing the recommendations contained within the Atlantic Menhaden Draft Addendum II. There is sufficient evidence and support for further restrictions on the amount of reduction fishery harvest permitted in the Chesapeake Bay.
I support Virginia's businesses, but one company should not be permitted to over-harvest the menhaden to the detriment of other users and the ecological health of the Bay. The current restrictions are insufficient and illogical, and the proposed management program is a step in the right direction.
As for the specific additional restrictions, I defer to professional staff for their recommendation, but it must accomplish the goal of restoring the menhaden population in the Bay to a sustainable level.
Osprey chicks are not receiving sufficient food because the menhaden population is too low. The striped bass population is down. And the population of menhaden in the Bay is down.
Something must be done to restore the menhaden population to a health level.

Sincerely,

Michael Coughlin

I have been a Menhaden fisherman full time since 1974. I began in 1971 during school vacations. My daddy was in the business before I was born. Although I've been fishing the Gulf for awhile now my career began fishing out of Beaufort, NC. I guess my strongest argument against farther restrictions on the Bay Area would be six Omega Protein Fishing boats and two bait boats can never hurt the stock in a million years. That's eight two purse boat rigs on the entire East Coast. Common sense says that few boats can not hurt a fishery that has thrived out of Reedville for over 100 years. Thank You, David Yates retired menhaden Captain

It's extremely important to cut back on menhaden annual harvest. We need stricter quotas and caps. The entire eco system relies on this precious resource. DO NOT OVERHARVEST. It's time to cut back. We need drastic measures now.

Do not wait until we lose it all. The signs are in place, do not ignore the warnings!

I have lived on Timberneck Creek for 10 years.
I watch the water daily.
Last summer, the osprey failed to produce a hatching. This year, one was produced, but died.
Seeing porpoise used to be almost a daily delight. This year I may have seen them 4 times.
There's no food.
Before this year, I could listen to fish jumping in the pier lights. That has virtually stopped. There's no food.
I urge you to substantially reduce menhaden limits and strictly enforce them.
In the early'90's you could virtually walk across the recreational fishing boats on the York River. Now, you're lucky to see 4.
There's no food!

Dear Commissioners:

I am a process engineer at the Omega Protein reduction plant in Reedville — the last menhaden reduction plant on the Atlantic coast. I am not an industry spokesman and I was not asked to write this; these are my own comments. I don't fish for a living, so I'll confine myself to what I can speak to with certainty: the effect of Draft Addendum II's timing structures on shore-side plant operations, and the record you already have in front of you.

On the cap (Section 3.1). The current 51,000 mt cap already represents a 53 percent reduction from the 109,020 mt set as a precaution in 2006, and Bay landings have come in under the cap every year of its existence except 2019. Bay harvest also counts against Virginia's state allocation, and the Board has already cut the coastwide TAC 20 percent for 2026. A further one-time cut of 10 to 50 percent (Option B) would be pure precaution — not a response to any finding about the Bay — taken while the research this Board says it needs is finally funded and underway: $2 million to VIMS from Virginia, a $2.5 million federal earmark, and an industry-supported study already in progress. Any move below Option A should wait for those results. Option C, which links the cap to the coastwide TAC, should be treated as what it is: a standing, automatic cut that transmits every future TAC vote straight into the Bay without a separate Bay-specific finding.

On quota periods (Section 3.2.1). I don't dispute the Board's premise that concentrating over half of Bay landings in a six-week midsummer window, as happened in 2023 and 2024, is a working hypothesis worth investigating. Your Plan Development Team said plainly its analysis was inconclusive at the resolution evaluated — and it also could not rule out that the concentrated 2024 harvest affected upper-Bay availability. That is exactly why the funded research matters, and why I accept the Board may act on timing. But the structure chosen should not quietly become a deeper cut. An option allocating half the cap to the final period (Option B2, 50 percent across September 13–November 19) allocates the quota to the weeks when both weather and the menhaden's own seasonal movements make Bay harvest least reliable. Quota that goes uncaught in the Bay is not conserved coastwide — the same fish are still taken against the coastwide TAC once they leave the Bay, and the Bay fishery absorbs the loss. If the Board wants a real reduction, it should make that case under 3.1 and weigh it honestly. If it wants to moderate timing, Option B3's uneven periods — which preserve a genuine midsummer operating window — are the least damaging structure on offer. And the Commission's own presentation on this addendum acknowledges that seasonal restrictions may constrain periods of high catch efficiency and limit processing throughput. Let me make that concrete from the plant floor. Menhaden is among the most perishable raw materials there is — landed in the morning, running through the plant the same day. Our schedules, crew rotations and maintenance planning are built around a predictable, midsummer-centered season. Forced idling in good months followed by maximum-rate operation in hurricane season does not average out; it stacks reliability risk on an irreplaceable plant. If periods are adopted, quota-period paybacks (Section 3.2.2, Option B) should be rejected — they add pressure to fish marginal weather days to avoid next-year forfeitures, the opposite of the safety margin crews are trained around.

On the osprey question, some honesty from my side. I won't tell the Board there is nothing wrong in the Bay. Peer-reviewed work from William & Mary's Center for Conservation Biology links starving chicks in menhaden-dependent areas to prey shortage, and the recent multi-state survey found only about 28 percent of saltwater nesting areas producing enough young. What I will point out is that the same researchers name two possible causes: prey quantity, and menhaden entering the Bay later in the breeding season. Our own season started about five weeks late in both 2023 and 2024 — meaning that in those springs, pound-net catch rates were below average before the reduction fishery had put a net in the water. What's driving the shift — environment, abundance, distribution, or some combination — is precisely what the funded studies are designed to untangle. Punishing the Bay fishery's annual tonnage for a timing problem the coastwide cap cannot fix is not the tool that fits.

Reedville has processed menhaden for well over a century. What the Board decides in November determines whether the last reduction plant on this coast keeps a workable operating pattern — not whether the fish get caught somewhere else, but whether they're caught by the people of one small town. Please keep the cap at status quo, keep any timing structure workable, and let the science decide the rest on the three-year revisit clock.

Pulling out the bottom of the food chain and pretending that it will be okay is beyond stupid. Don't let corporate greed and their associated hush money destroy the Bay and all of the life that depends on the menhaden!! Be responsible to the citizens who own the Bay and not Omega Protein who are leeches!!
Stand up for what is right - tell Omega Protein to LEAVE THE MENHADEN IN THE BAY!!!!!!!!!

As a raptor rehabilitator, I have seen alarming changes first hand to the Chesapeake Bay's Osprey population. Juvenile Osprey are suffering from starvation from the lack of Menhaden. The past three years have been catastrophic to Osprey. Now is the time to take strong action to ensure the menhaden population is healthy and can support all life on the Bay.

I support reducing the cap by 50 percent in 2027 and implementing quota periods to more effectively distribute reduction fishing pressure throughout the season.

Specifically, I support the following options in Draft Addendum II:

3.1 Chesapeake Bay Reduction Fishery Cap Amount: I support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, I support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.

3.2 Chesapeake Bay Cap Distribution: I support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. I also support option B

which establishes quota period overage payback and rollover of unused quota within a fishing year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: I support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

Thank you

Malia Hale

Founded in 2002, Owl Moon Raptor Center is a state and federally licensed wildlife rehabilitation center specializing in birds of prey. Our mission is to rescue and rehabilitate injured, sick, and orphaned birds of prey and return them to the wild in sound, athletic condition, and to educate the public about raptors in the process. Owl Moon is located in Boyds, Maryland and serves the entire state of Maryland.
Over the years, Owl Moon has treated hundreds of Osprey that have come in sick or injured. Typically, young Osprey are admitted to Owl Moon after encountering trouble while learning to fly. Returning a nestling to its nest, or placing it in a foster nest after injuries are treated, was common and largely successful. However, beginning three summers ago in 2023, an alarming number of juvenile Osprey were admitted suffering from starvation. In 2024, the number of Osprey admissions doubled, going from 48 in 2023, to 93 in 2024, with 66% of the juveniles in emaciated body condition. Many of these juveniles were extremely lethargic and weak, often dying within 24 hours of admission. Many others died after 3-4 days, suffering from refeeding syndrome.
In 2025 and 2026, Osprey admissions declined overall, with an unusually low number of juveniles admitted. Based on calls received and outreach to on-the-ground scientists, we believe many juveniles unfortunately died while still in the nest, without ever making it into care and rehabilitation, and survival rate of those admitted to Owl Moon was low.
A recent study from the William and Mary Center for Conservation Biology noted that 2026 was the worst Osprey season they

have ever documented. Our numbers this summer are consistent with those findings. Juveniles made up almost half of the total patients and of those juveniles, 70% were emaciated.

It is clear from our perspective at Owl Moon that the Osprey population in the Chesapeake Bay is crashing. Juveniles are either dying in the wild or soon after they arrive for care. They are too weak from malnutrition to survive. Osprey depend on menhaden after returning from South America, to prepare for the breeding season. Once chicks have hatched, menhaden become critically important to their growth and survival. It is clear from the Center for Conservation Biology's report that those Osprey depending on menhaden as a primary food source are unable to properly feed their young, and as a result nest failure is dramatically increasing not only in the Chesapeake Bay, but also along the east coast. This is a crisis, and immediate measures must be taken now.

The proposed Addendum by the Atlantic States Marine Fisheries Commission, to reduce and reschedule industrial menhaden fishing in the Chesapeake Bay, is necessary now. The Chesapeake Bay menhaden fishery cap should be reduced to zero, to properly address the crisis happening now in the Bay. In addition, creating quota periods would distribute the menhaden harvest throughout the fishing season and allow more opportunities for Osprey to have access to menhaden in critical ecological periods such as nesting and fledgling seasons.

The Chesapeake Bay is home to the largest population of Osprey in the world. There is consensus that the population is in serious decline. Now is not the time to simply fund more studies or make a less-than-meaningful cut to the cap. If strong action is not taken now, scientists predict the population could decline by half in the next 10 years. We no longer have time to wait.

As a concerned stakeholder, I want to thank you for the opportunity to comment on Draft Addendum II. I support the following management option.

3.1: Options C1e and C2a. I support a precautionary reduction in the Bay Cap by 50% of the current 51,000 metric tons for the reduction fishery. This will help increase the number of menhaden available in the Chesapeake Bay, an important nursery for Atlantic menhaden.

3.2: Option B2. I support the establishment of three quota periods for the Bay Cap at a 25/25/50% harvest distribution percentage per quota period. This will help reduce food competition for birds like osprey during the most vulnerable times of their life cycles.

3.3: Option B. I support reviewing the Chesapeake Bay Cap every 3 years. This gives the Commission the ability to plan and react to changing conditions and new information.

Thank you for caring and taking your part in saving these magnificent birds.

As behalf of the Maryland Ornithological Society (MOS) and our 2600 members, I urge the ASMFC to choose the maximum reduction in the Chesapeake Bay Reduction Fishery cap for the Bay, preferably a complete cessation of the menhaden harvest by purse net factory fishing to allow its population to recover.

Failing this we favor;
Sub Option B4: 50% reduction, resulting in a Bay Cap of 25,500 mt

We are very concerned about that decline in the ospreys and predator fish and deplore the undue deference given to the reduction fishing business at the expense of the Bay ecosystem.

Please we need limits on the fishing of Menhaden immediately! We have worked so hard in Chesapeake Bay and all its tributaries to maintain and improve the Osprey population and now with their food source diminishing they will not recover!!!! Something needs to be done to prevent the large companies fishing the main source of the Ospreys food supply on the East Coast. We need everyones help now.

Bunker are a public resource that needs to be shared among numerous users and as a publicly owned resource, highest value use should control. Grinding up the vast majority of this "most important fish in the ocean" by one foreign company employing a few hundred people to create something readily available elsewhere is a very low value use of this community owned resource. And selfish. It is yesterday's low value industry using today's technology to deplete all of our fish.

Anyone who's ever been on the bay can see there's a fraction of life left compared to even 5 years ago,never mind about the good ol days. Hardly ever do we see the birds working schools of fish . Nor can you count on catching striped bass coming out of the York river. The only menhaden you see are when foreign owned fleets are scooping them up EVERY DAY in the Chesapeake bay because They are allowed hundreds of thousands of metric tons of one of the most valuable resources of the food chain that Virginia has . No group or individual or lobbyist should be granted this right to pillage and rape a watershed of its most valuable link on which multiple species survive on . It's not the recreational sportsman that needs restrictions , it's the million ton guys that need microscopic scrutiny . Thank you for your attention to this matter. Gary Lowe. Yorktown Va.

Dear Members of the Board,
I am writing to you as a lifelong resident of Connecticut and the East Coast who grew up loving the wildlife and waters around us that we all cherish. I urge you to pass the Addendum that will reduce the current fisheries cap. We must do our part as a humanity to support the wildlife around us and protecting such fragile ecosystems not only for the wildlife and vegetation that enriches our lives but to ensure a healthy future for us all. If things remain the way they are, we may see further devastating species depletion and further ripple effects. Please do the right thing. We have the chance to do the right thing and help ensure a bright and healthy future.

Thank you for your time,
Nicole Vesey

I am urging you to protect the osprey and menhaden populations by adopting substantially stronger, ecosystem-based management of menhaden by adopting a 50% reduction in the industrial harvest, or by totally ending industrial menhaden reduction fishing along the East Coast or by closing the Chesapeake Bay to industrial harvesting until independent science demonstrates that the fishery is not harming the ecosystem.
Menhaden are the most important fish in our coastal waters. As filter feeders, they consume phytoplankton and algae, helping to improve water quality. They are also a foundational food source for many iconic Atlantic species, including striped bass, red drum, bluefish, ospreys, pelicans, dolphins, and whales.
This year's breeding season has been devastating for ospreys along the Atlantic seaboard. Researchers, wildlife rehabilitators, and conservation groups have documented widespread nesting failures, with many chicks starving, adults struggling to find enough food, and some parents abandoning their nests because they cannot feed both themselves and their young.
Please act and reduce the menhaden fishing quota by 50%.

I grew up sailing and fishing on the Chesapeake Bay and continue to do so to this day. The only thing is in recent years - the fish are not plentiful, my recreational fishing hook remains empty, and the channel makers I pass along the way are empty of osprey. Please bring this Addendum II to fruition and make real efforts to implement commercial overharvesting and provide protection to Chesapeake Bay wildlife in and above its waters. Please do so for the wildlife and future generations who should know what its like to catch a fish in the Bay or see an Osprey capture its prey.

It is my hope that the fisheries commission will do something about managing Chesapeake. The current policies and overfishing created fish large enough to have severe impact on the Delta population population offspring population and. Although we need more studies, there's enough evidence of the case.

As a biologist, I can attest to the importance of protecting our coastal ecosystems...both for the animals and plants that live there, and also for us! Please, do everything in your power to protect the ospreys and the fish they rely on for their very survival. No effort is too small or too great. What we do to the web of life, we do to ourselves.

While there may not yet be scientific evidence establishing a direct link between menhaden abundance and the decline in numbers of numerous species, the evidence is clear that the health of the Chesapeake Ecosystem is in serious trouble. The historical record of our abuse of the priceless resource is also very clear. We are at a critical point in the health of the Bay. It would seem prudent to place stricter limits on harvest of menhaden until the situation can be investigated, rather than wait until the entire fishery has collapsed to decide to act.

Stop allowing reduction fishing in the bay, leaving the bay as a nursery for menhaden as nature dictates. Doing otherwise will eventually lead to the fall of the Chesapeake Bay. My question is why is Virginia the only state left on the East coast that allows this type of fishing? All other East coast states have banned mass fishing and reduction fishing based on studies. Are they all wrong? There is only one reason why reduction fishing is allowed in Virginia...money. Considering the location of a processing plant minutes from the 3 mile limit for reduction fishing Omega Protein (Cooke, Inc.) must be saving millions. So who gets their savings? How much does the state get? Have you considered the income the state COULD be receiving for tourism from anglers, nature lovers, boaters etc. What happens when Omega pulls out of Reedville because the fish are no longer there? Don't think that will happen? Think again! Do the right thing...push them to the Atlantic with regulations that will be upheld and save the bay for future generations. If you don't then better hurry and change Virginia's state slogan!

Bill Cavers, Interim Executive Director, Connecticut Audubon Society
Summary of Testimony given to the Atlantic States Marine Fisheries Commission on September 16, 2026

My name is Bill Cavers. I am the Interim Executive Director of the Connecticut Audubon Society. We are headquartered in Fairfield, Connecticut. We have nearly 9,000 members, and 6 regional centers across the state – including 3 on the coast. I'm testifying to you tonight to urge you to adopt the 50% Bay Cap reduction. Why? For the most precaution.

Our Viewpoint
We are not fish experts, but we're committed Conservationists and we have a particular focus on Ospreys. Since 2014, we've run our Osprey Nation Program in partnership with CTDEEP. It monitors the size, productivity and health of Connecticut's Osprey population. Approximately 450 volunteer stewards monitor nearly 1,000 nests each season. Last year, our program recorded its lowest breeding success ever. This year is looking even worse.

Matt Joyce, our Conservation Science Manager, testified to our specific findings. But from the Executive Director perspective, I would just like to impress upon you how deeply our organization and its members care about our Ospreys and this year's

alarming breeding season. You yourself can witness this care online:

1) We set up an “Osprey Cam” at our Milford Point Coastal Center this year and linked it to our website. Since March, it has received over 28,000 views! This surpasses, by far, anything else we've posted on the website.

2) We set up a now independently run Facebook page, Osprey Stewards of Connecticut. On it you’ll find our volunteers posting endearing pictures and videos of their nests and charges. The posts reveal heart-felt care for these beautiful birds and their place on the Connecticut shoreline.

Our Advocacy
To be precautionary, to acknowledge the key role that Menhaden play in supporting Connecticut’s Osprey populations, we urge you to take the following decisive action:

- Adopt Sub Option B4: a one-time 50% reduction in the Bay Cap
- Adopt Quota Period B2: 25-25-50% allocations to delay seasonal harvests

On behalf of Connecticut Audubon's members and our Osprey Nation stewards, thank you for listening.

Bill Cavers
Interim Executive Director
Connecticut Audubon Society

Dear Atlantic States Marine Fisheries Commission Members,

Menhaden are an important part of the ecosystem of the Chesapeake Bay, as a food source for birds and other fish, and as a key forage fish species that are relied on by costal communities. Ensuring the health of the menhaden population is important for many, particularly the struggling Osprey population.

The ASMFC's focus on utilizing ecological reference points (ERP) to manage the menhaden population is appreciated, as is your interest in hearing from the public on Draft Addendum II.

I support the following options:

3.1: Options C1e and C2a. This precautionary approach would reduce the Bay Cap by 50% of the current 51,000 metric tons, which would recognize the importance of the menhaden population to the Chesapeake Bay ecosystem.

3.2: Option B2. To help reduce food competition for birds like osprey during the most vulnerable times of their life cycles, I

support the establishment of three quota periods for the Bay Cap at a 25/25/50% harvest distribution percentage per quota period.

3.3: Option B. Reviewing the Chesapeake Bay Cap every three years will give the ASMFC the information with the ability to plan and react to changing conditions with updated information.

I believe these options will optimally support a healthy Chesapeake Bay ecosystem, which is what is best for not just the fish, birds, and other animals, but the people and the Earth.

Thank you for the opportunity to provide comment on the draft Addendum II to Amendment 3 to the Interstate Fishery Management Plan.

Sincerely,

Deborah J. Glick
New York State Assemblymember, District 66
Chair, NYS Assembly Environmental Conservation Committee

I support the 50% cap on the menhaden catch and quotas to distribute the catch to better promote the health of the menhaden population. Much more must be done to promote the restoration of this species in the Chesapeake and through-out the Mid-Atlantic. 60 years ago the waters off New Jersey were black with vast schools of menhaden. Today they have all but disappeared. The efforts to restore the Chesapeake fishery should be the start of an all-out effort to bring this population back and the many other species that depend on it.

I am both a commercial and recreational fishermen. I realize the importance of having a sustainable fishery that over harvesting dosent occur so we don't put ourselves out of buisness. But sometimes it's a hard choice if you have to protect what also affects the financial decisions for every day living.
But I'm a firm believer that taking the necessary harder cuts now will pay off sooner than later and kicking the can down the road. Rebuilding at a higher stock than waiting until the bare minimum level will ultimately come back sooner. I don't have enough info to say what percentage has to get cut back but I think taking the firmer approach will hurt now but the benefit will out perform in the long run.
Hoping for a healthy fishery soon.

I am 100% against any more cuts, quotas, or limits to the menhaden fishing industry located in Reedville, VA.
Doing so, would be a horrible travesty to our small town, our economy and our jobs!
Our industry and residents have been harassed by these sport fishing groups, for decades, who see no limits to close down a 148 year industry that is being managed by many agencies with quotas and limits. The amount of hate, misinformation and lies in articles, magazines and social media has been abundant.
Their latest ploy is saying the menhaden are overfished and the osprey are hungry. The bald eagles, which are no longer endangered, play a huge part in the demise of the osprey chicks. They are seen scooping up the babies and stealing the nests. The adults move to new locations and are seen healthy in new areas where they relocate.
The environmental groups, who are in this “close Omega down” campaign don’t talk at all about the sewage dumped into our rivers and streams, how many new properties are built near the water with run off resulting. They try to blame everything on Omega so they can get more money for their organizations, spewing misinformation by creating some crisis while not addressing others.
Omega Protein/Ocean Harvesters are great stewards to the communities, offer good paying jobs, health insurance, 401k plans, educational aid and a family atmosphere for their workers.
Many generations have worked with the fishing industry as Captains, Mates, Pilots, Bosons, crew, fish spotters, plant employees, and office personnel.
My father-in-law was a Captain, my husband a vessel Chief Engineers, my son a boiler operator, my granddaughter a new

employee this summer. Our neighbors were captains. Now their grandchildren are fishing, plane spotters,etc.
I retired in March, 2025 after 49 years in the office, shipping meal, oil and solubles, accounts payable, Quality Control Lab, and the last 25 years keeping records for the many agencies that manage the fisheries.
It is sickening to see the lies and misinformation these groups say about my past work family.
In the meantime, while waiting for the new investigation about the menhaden fishing situation, leave everything as is until science proves there is a problem!
I was glad you all made the trip to Heathsville to hear the heartfelt testimonies and observations from those hardworking men and women who call this company their work family. Reedville is truly a gem and the fishing factory is the reason behind this town's success.
Susan D. Haynie

My name is Peter Mohlin and I am a recreational saltwater fisherman from Maine commenting on the Atlantic Menhaden Draft Addendum II. I support the following options under this draft Addendum II:

3.1 Chesapeake Bay Reduction Amount
Sub Option B4 – a 50% reduction in the current Bay Cap, resulting in a Bay Cap of 25,500 mt.

3.2.1. Chesapeake Bay Reduction Fishery Cap Quota Period
Option B1 – Even Length & Even Harvest.

3.2.2 Chesapeake Bay Reduction Fishery Cap Quota Period Overages and Underages
Underage Sub Option 1 – an underage in Quota Period 1 would be split evenly and rolled over to Quota Periods 2 and 3.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision
Option B – The Chesapeake Bay Cap will be reviewed at least once every three years.

Please do the right thing and enact measures to protect this valuable fishery so all stakeholders can sustainably enjoy this resource.

At one time there was over Twenty Menhaden Factories on the East Coast. North Carolina banned Menhaden Factories years ago. Now there only one left. If closing nineteen factories and shutting down fishing for Menhaden in North Carolina haven't helped. Then I don't think changing the Quota is going to help anything. Something not yet determined is affecting the Menhaden population.
I hope someone figures it out.....

Dear Members of the Atlantic States Marine Fisheries Commission:
As a resident of Niantic, Connecticut, I am the co-founder of Pandion Partners, a volunteer organization dedicated to repairing/replacing aging and weathered nesting platforms. I strongly advocate for reducing the Chesapeake Bay Atlantic menhaden fishery cap by 50%.

I have been involved with osprey restoration in southeastern Connecticut since 1974, erecting 30 artificial nesting platforms and having participated in the CT-DEEP osprey banding efforts until 2014. I have witnessed both their recovery and their recent decline.

The recent reduction of the Connecticut osprey productivity is alarming. At Great Island in Old Lyme, 37 Osprey chicks fledged in 2024, 27 in 2025, and only 5 in 2026. Statewide, reported nest failures through August 1 also increased substantially. These declines should be viewed as an important warning about the availability of prey in our coastal ecosystem. Ospreys are highly visible indicators of marine ecosystem health, and declining reproductive success deserves a precautionary response. Menhaden are not simply a commercial resource. They are a critical forage species supporting Ospreys, striped bass, bluefish, and many other predators. Removing large quantities of menhaden from the food web reduces the prey available to osprey during the breeding season.
I urge the Commission to reduce the Chesapeake Bay menhaden harvest cap by 50%. Maintaining a larger menhaden

population will provide a greater margin of safety for ospreys and the broader marine ecosystem.
As a Connecticut resident who has personally witnessed changes in our local osprey population, I believe we should act now rather than wait until further declines occur.
Thank you for considering my comment.
Sincerely,
Greg Decker
Pandion Partners

The fishery is in dire straights, in 5 years the Osprey and the Fish (ALL) population will completely collapse and we will all be in real trouble and those profiting will only move on and leave the mess to fix after it is too late:

Lets us be smart here and lets share in the benefits of the Menhaden- as this is a real option.

In response to the options contained Atlantic Menhaden Draft Addendum II, the Hi-Mar Striper Club selects and endorses the following:

• Bay Cap Amount: Sub-Option B4 – a 50% reduction resulting in a 25,500 mt cap
• Quota Periods: Option B1 – even length periods with evenly distributed harvest.
• Linking the Bay Cap to Total TAC: – Option C1e. – 50% Reduction linking the Bay Cap to Coastwide TAC (25,500mt – 2027)
• Underage Provisions: Underage Provisions Sub-Option 1 -roll Period 1 underages evenly into Periods 2 and 3.
• Revisit Provision: Option B – revisit the Bay Cap every three years.

My opinion following extensive reading concerning Osprey reproduction devastation in the Bay areas where they depend on Menhaden is either ban such industrial level fishing in the Bay or significantly reduce the catch. Waiting for under funded research that proves what Bay fisherman and conservationists already know could doom theses magnificent birds as well as thousands of fisherman's livelihoods. The Osprey survived the DDT fiasco, let's save them again. There are plenty of unfilled jobs in Virginia for displaced reduction workers. Further, I believe the last working reduction industry here is forigen owned. That is NOT Making America Great Again!

As a marine science student attending university, and someone who lives at the Jersey shore, it is so important to me that menhaden be protected and their fishing regulated, so that other species such as the osprey can thrive. Without Atlantic menhaden, young ospreys starve to death, as we have seen this past season. I urge you to please put a tighter cap on menhaden fishing, and implore you to work to implement and enforce policy that will help rebuild this critical food web, and others like it.

Dear Atlantic States Marine Fisheries Commission, I support adoption of the Draft Addendum II, which intends to reduce the Chesapeake Bay menhaden fishery cap by up to 50% and create quota periods to more evenly distribute the harvest throughout the fishing season. Although this will likely have negative consequences for some commercial harvesters -- particularly industrial harvesters serving the demand for vitamin and mineral supplements -- these considerations are outweighed by the risk of much deeper and longer-lasting negative economic impacts for the Bay's entire marine life ecosystem. Thank you for considering my opinion. Mike Ashford

The over fishing of the Chesapeake bay has many environmental repercussions. I'm concerned that the birds, specifically Osprey, have had a serious decline and their nesting has completely failed, chicks are starving to death. This has been documented by the Audubon Society. Other birds rely on this food source, the bald eagle and the lesser birds, terns and seagulls.
So, a drastic reduction is necessary and especially during the nesting season. Which starts in May in case you are unfamiliar with avian behavior.

Thank you
JUNE BOURDAT

As a person who has grown up around the bay and appreciates the value it brings to both wildlife and residents, I support the stricter regulations for protection of the manhaden fish. As I am sure you are aware, menhaden fish, are important for the survival of every fish-eating bird that shares their habitat, especially ospreys, and marine life including striped bass, bluefish, redfish, bluefin tuna, humpback whales, dolphins. The benefits Virginia seeks by the continues use of industrial reduction fishing, is far outweighed by the harms this type of fishing causes to the health of the bay and the wildlife that depends on it for their survival. For these reasons, I strongly support stricter regulations as soon as possible.
Thank you.

I am both a commercial and recreational fishermen. I realize the importance of having a sustainable fishery that over harvesting dosent occur so we don't put ourselves out of buisness. But sometimes it's a hard choice if you have to protect what also affects the financial decisions for every day living.
But I'm a firm believer that taking the necessary harder cuts now will pay off sooner than later and kicking the can down the road. Rebuilding at a higher stock than the bare minimum level will ultimately come back sooner. I don't have enough info to say what percentage has to get cut back but I think taking the firmer approach will hurt now but the benefit will out perform in the long run.
Hoping for a healthy fishery soon.

Menhaden serve as a critical forage species along the U.S. Atlantic coast, transferring primary production to higher trophic levels. Commercially and recreationally important fishes, including striped bass, bluefish, spiny dogfish, and bluefin tuna, are all known predators of Atlantic menhaden (Anstead et al. 2021). Avian predators, including osprey and bald eagles, also feed on seasonal menhaden aggregations, as do sharks, weakfish, and marine mammals including bottlenose dolphins and humpback whales (Ahrenholz 1991; Anstead et al. 2021). For each of these species, menhaden schools represent a predictable, energy-rich prey source that is particularly exploitable in nearshore habitats during their seasonal migrations. Predator health and recruitment have been tied to menhaden abundance in estuarine environments (Uphoff 2003). Decreased menhaden populations were implicated in the depressed nutritional state, fluctuations in weight-at-length and weight-at-age averages, and spread of disease observed in Chesapeake Bay striped bass during the late 1990s (Uphoff 2003). The presence of stable menhaden populations has also been identified as a potential predictor of nesting success and productivity in osprey in the lower Chesapeake Bay (Academia and Watts 2023; Watts et al. 2024). These cascading trophic interactions highlight the importance of maintaining adequate menhaden abundance throughout coastal and estuarine ecosystems. Their abundance supports the feeding demands of a large and diverse predator base, and documented shifts in menhaden abundance have been associated with impacts on the health and productivity of upper-trophic-level populations within their communities.
Estuaries including the Chesapeake Bay serve as important nursery habitat for menhaden, but environmental conditions within the Bay are also changing. Summertime temperatures in the Chesapeake Bay have risen steadily since the 1980s,

while the volume and duration of summertime hypoxia have also increased (Nelson et al. 2025). These environmental changes may impose additional physiological and ecological pressures on menhaden populations within the Bay.
Draft Addendum II is a response to growing concerns over declining pound-net harvest and reduced catch per unit effort in the Chesapeake Bay. These declines, considered in the context of environmental degradation and continued fishing pressure, warrant a precautionary management response. Where environmental conditions are becoming increasingly challenging, maintaining sufficient menhaden abundance may be particularly important for supporting both menhaden populations and the ecosystems that depend upon them.
Given the ecological importance of menhaden throughout their range, additional management action is warranted to improve menhaden survivorship and maintain adequate forage availability for dependent predators. I support selecting the 50% reduction option for the Chesapeake Bay Reduction Fishery Cap and encourage the ASMFC to adopt the maximum reduction currently under consideration in Draft Addendum II. Reducing harvest would provide refuge for menhaden in an important estuarine habitat at a time when increasing temperature and hypoxia may impose additional environmental stress. I also support measures to distribute reduction harvest more evenly throughout the fishing season, reducing the potential for concentrated removals to affect menhaden availability to other fisheries and predators. This reduction should be viewed as an important first step in the continued management of the fishery, coupled with future integration of ecosystem-based fisheries management and robust environmental action that can work together to restore degraded ecosystems and consider not just menhaden abundance, but also the ecological requirements of the predators, fisheries, and ecosystems that depend upon them.

Comment

Hello,

My name is Scott and I am a lifelong Virginian native to Virginia Beach, an avid outdoorsman, and lover of the Chesapeake Bay. I've fished the Bay extensively for a couple of decades and have spent countless hours on the water. Because I love the Bay and the Atlantic as a whole, I am writing to advocate for the passage of the Atlantic Menhaden Draft Addendum II reducing the menhaden cap and dividing the harvest into seasonal periods. What Omega, Cooke, and Ocean Harvesters (I'll collectively refer to them as Omega as they are all the same) are doing calls for common sense regulation as more data is being collected. It is telling that Omega has lobbied extensively against that independent data collection in the first place. This addendum would serve to support local commercial watermen, recreational fishermen, bird watchers, whale watchers, and the American people who rely on the Bay for connection with nature, God, and each other. This over-consumption is unsustainable. While I recognize Omega has been fishing the Bay for decades, it is notable that it is taking them longer to fill their cap while they have greater access to advanced technology creating a more efficient harvest. The notion that a species cannot be over-harvested to decline or failure, which Omega continually asserts is the case for menhaden, is kindly untrue, but frankly ridiculous. Just ask Virginia elk, the passenger pigeon, or American bison. If you're reading this and have never seen one of the net sets in person, I'd be happy to take you out on my boat any time to watch it. While the bycatch of drum, rockfish, cobia, croakers, spot, etc. is heartbreaking, it is important to remember that the most important fish being killed in the nets are the menhaden. My wife and I are returning to the Tidewater area in the coming year and a massive piece of that

decision is to show our son the Bay that we know and love. Omega's consumption has already changed the Bay enough (ask anyone who actually spends time on the water). A large number of us, with actual fisheries and environmental experts in this group, have legitimate fears that if left unchecked Omega will kill the Bay. This addendum would be a phenomenal step in the positive direction. The public outcry is strong for a reason and I ask that you listen to Americans up and down the coast! I urge you, as officials tasked to foster the Atlantic, please protect our resource now and pass this addendum in full.

Thank you from all of us!

Scott

I believe that an ecologically healthy bay and a strong commercial fishery can co-exist, but recovery of fish numbers comes first. I strongly support the cap reduction, along with common sense approaches to the mitigation of the impact to the extent possible (but recovering fish stocks takes priority).

I am writing to strongly urge ASMFC to reduce the Chesapeake Bay reduction fishery cap by the full 50% and implement quota periods. As a Maryland resident who cares deeply for the Chesapeake, it is heartbreaking to see the impact of depleted menhaden abundance on all the species which depend on these fish for survival. Please place the health and survival of our native species and ecosystem over corporate profits. You have the power, opportunity, responsibility and indeed obligation to act. Thank you.

I am very concerned about the drastic decline in Ospreys along the Atlantic seaboard, particularly in the Chesapeake Bay, which saw almost no healthy young during this past year's breeding season. We have all come to love the dramatic "fish hawks" as they dive for fish to feed their young. Their comeback from the impacts of the widespread use of DDT during the post WWII years was heartening. We began to think our environment was recovering from misguided practices. It's distressing to know that the overfishing of menhaden, the primary sustenance Osprey need for their young, is causing these majestic creatures to once again decline here in Rhode Island. Once company seems to be responsible because of its overfishing all along the Atlantic Coast. Placing restrictions on the catch is the only rational and feasible way to bring our Ospreys back.

I am worried about the health of the bay and see problems with the excessive catch of menhaden which is allowed by the ASMFC. I know the striped bass population is under stress and there has been an unfortunate loss of osprey. Those who study birds have seen osprey chicks that die in the nest because of lack of food. If ASMFC will reduce the amount of menhaden commercial fishermen are allowed to catch, that will help the bay heal and hopefully rebound with its abundant eco-system.

It is imperative that the menhaden catch currently allowed by the state of Virginia be sharply curtailed. I have first hand experience with the Osprey die off. That all Americans must suffer this loss because of, at best, short sighted politicians and, at worst, politicians beholden to special commercial interests, is both sad and infuriating. Why should the state of Virginia have the power to unilaterally decide to starve the osprey (and other less visible wildlife) of the Chesapeake Bay? Of course it should not. Please do the sensible and decent thing and drastically curtail the allowed catch. Last summer, I heard the desperate Osprey mother endlessly calling for her mate to return with food for their chicks. They all starved. This year, only one adult bird returned. Another failed season. Not just this particular nest, but virtually all nests in the region of the Chesapeake Bay where I live. An incredible come back story knee capped for dog food and fish farms. And adding insult to injury, perpetrated by a foreign company (yes, technically a US company, but only by a wink and a nod). Please realize that American wildlife is special and drastically reduce the allowed menhaden catch.

The menhaden harvest needs to be reduced by at least 50%. It should actually be reduced by greater than 50%. It certainly shouldn't be reduced any less than 50%. A huge reduction in menhaden harvest is needed. Osprey and almost every predatory fish depends on them as a food source. The commercial fishing industry shouldn't be allowed to annihilate the population of menhaden, resulting in the decline of ospreys, striped bass and other fish.

I live on the river and am aware of the declining number of osprey. Please take action to limit the number of menhaden that can be caught by fisherman. They don't need them to survive, but the osprey do.

I'd like to see more menhaden left in the ocean. They're the backbone of all sea life and I've seen changes in my 26 year life in loss of life due to decreased menhaden numbers. Especially with poor striped bass recruitment, we need all the "pogy" we can get.

To the ASMFC Atlantic Menhaden Board

My name is John Page Williams. I am a Virginia resident now retired from a 46-year-long career with the Chesapeake Bay Foundation–much of it on the water and in the field. I have held an active USCG Master's license since 1977. In retirement, I remain active as an outdoor writer for several online and print publications, as well as a volunteer fishing/ecology guide on Virginia's tidal rivers.

For thirty years or more, I have been concerned about Chesapeake Bay menhaden as well as the species and communities dependent on a healthy menhaden population, not only in Virginia and Maryland but all the way up the coast through Downeast Maine, where the lack of herring for lobster bait is placing ever more pressure on the total coastal stock of menhaden. With all due regard to the local people and economy of Virginia's treasured Northern Neck, where I have deep roots myself, there are many, many more jobs dependent on the Chesapeake's stock of menhaden than just in Northumberland County alone, to say nothing of satisfying needs of iconic wildlife–from ospreys and rockfish to tuna and whales–that have depended on these forage fish literally for millennia.

The Chesapeake Bay is changing and showing increasing signs of stress. I have seen it with my eyes, felt it in my hands, seen it on my skiff's sonar, read its numbers with YSI water quality equipment. Protecting menhaden is one of the truly

valuable ways we can help this struggling estuary and the Atlantic coastal ecosystem of which it is such a vital element. I would greatly appreciate you adding my signature in support of the following options in Draft Addendum II:

3.1 Chesapeake Bay Reduction Fishery Cap Amount: Support option C1e that would reduce the Bay Cap by 50 percent and limits it to 13.6 percent of the Coastwide Catch Limit (TAC). Also, support option C2a which sets an upper limit of 51,000mt for the Bay Cap, which is the current level.

3.2 Chesapeake Bay Cap Distribution: Support option B2 which establishes three even length quota periods for the Bay Cap, but distributes harvest 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. Also, support option B which establishes quota period overage payback and rollover of unused quota within a fishing year.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: Support option B Revisit Provision to reassess the efficacy of these new management tools every 3 years.

Sincerely yours,

John Page Williams

There needs to be quotas and there needs to be monitoring. I have fished the nj/de/md coast for 30 years. The menhaden serve as the base of the food chain and over the last 5 years I have witnessed a reduction in their numbers that I cannot begin to quantify. The amount of draggers 30 miles offshore fishing with airplanes is staggering. These schools of fish don't stand a chance and the predators that depend on them are in a state of decline. Recreational fishing for stripers, tuna, etc has declines significantly since I have started seeing the menhaden draggers out there. In addition we have an osprey nest adjacent to our home. Not one juvenile has survived the last two years. The predators are starving in Delmarva for fish oil pills - it's going to be a problem.

To Whom it may concern,

The menhaden population in the Chesapeake Bay area is one that is low on the food chain, and thus vital to the survival of not only ospreys, but also bald eagles, bass, trout, bluefish, bald eagles, pelicans, herons, gannets, and other wildlife.
We can check Osprey nests and see that there are either no eggs, or the infants are starving.
We cannot look into the oceans and see as easily how aquatic life is being affected, but if Ospreys are starving, so are the ocean fish that also depend on menhaden for sustenance. I find it unfortunate that the situation must become dire for a such a foundational species before any action is taken.

I therefore fully support Addendum II Amendment 3 to the Interstate Fishery Management Plan for Atlantic Menhaden. This includes implementing a bay cap of the full 50%, linking the Bay Cap to the coastwide total allowable catch, and distribution of the Bay Cap into three quota periods.

This needs to remain in place for several years to allow replenishment not only of the menhaden, but also of the animals that depend on them.
In my opinion, any review during this time should only be done to potentially lower the Cap even further if the menhaden are not recovering as quickly as expected.

Thank you for creating this addendum to allow the menhaden, and thus all beings in the food web dependent on them, the opportunity to recover so that we can help to ensure that a vibrant and diverse ecosystem will be handed down to our children and grandchildren.

Sincerely,
Lori Thomas

Cut the cap by 50% and distribute it across the fishing season as suggested. As a longtime resident of Shady Side, MD, who goes out weekly to fish on the water, I have seen firsthand the destruction this fishery has caused. Acres of water once teeming with menhaden at critical times of year is devoid of life, including the sportfish that depend on them. Pound netters cannot get the amount of fish they need to supply commercial crabbers with the bait they need. The West/Rhode river osprey populations, along with the 3 nests in our neighborhood and others on the western shore, have not been able to rear chicks for years. And as states look to improve water quality, does it make sense to remove tens of thousands of tons of a critical filter feeder from the picture? It doesn't take a rocket scientist to understand that removing the base of the food chain negatively impacts everything above it, including the livelihoods of recreational and commercial watermen who depend on them. And this goes far beyond Maryland and Virginia, as this is a forage species for fish and animals up and down the eastern seaboard. If the environmental implications can't be effectively argued, then someone needs to use the financial implications to quantify the damages and generate change. The Omega operation is short-sighted, unsustainable, and is killing multiple industries across multiple states. The fact they argue that jobs would be lost is both laughable and insulting considering how a few hundred people can put such a hurting on an entire ecosystem that supports hardworking men and women up and down the east coast. And arguing that the Atlantic stock is stable has zero to do with our localized bay stock, which is disproportionately affected and overfished. Other than Virginia, every other state has realized that this is a net-negative approach to the fishing industry, so why is this allowed to continue? While other states have found ways to boost stocks while simultaneously taking what they need for commercial fishermen (see Maine's Damariscotta fish ladder and their lobster industry), Ocean Harvesters

will continue to take, take, take until there is nothing left. Other than Omega and the politicians whose pockets they line, everyone will tell you that this fishery should not exist in any capacity within the Chesapeake Bay.

I am writing to ask that you make meaningful, downward changes to the total allowable catch for Menhaden in both the Chesapeake Bay and along the entire East Coast that you manage. I have been on the water for over 50 years, never have I seen Menhaden - bunker so hard to find, that includes Peanut Bunker I could be finding right now in the Jersey waters I fish and keep my boat. Cutting the bay cap in half is the bare minimum we should be talking about - I support more. The total allowable catch needs to meaningfully drop. Absolutely spread out the harvest to give some fish a chance to survive and reproduce and fulfill their part in the ocean/bay food chain. It is unfair one state holds all other states under their thumb; I support a more equitable distribution amongst all states.

I have zero issue with harvesting bunker for bait, crabs, lobster, recreational, etc. This type of harvesting brings dollars to all of our east coast communities and commercial sectors. Industrial or mass harvesting does not belong anywhere near our coastline or in our bays. If you boil this all the way down you are talking about supporting one company, Omega Protein, where the lion's share of the money derived from the fish they grind down benefits them, not the US. Yes, a small part of that income goes to a handful of people in Virginia, but you are looking at direct dollars that stay in the US of 100M vs 1B minimum if those same stay in the US. Most of the US bait harvest stays in the US, benefiting US-based companies up and down the East Coast. The AMFMC knows this, Virgina knows this, only political pressure continues to allow the status quo.

I feel I also have to offer my opinion of the politicization of this entire process. People should come first, not political donations

or potentially outright threats for suggesting we cannot continue down this path. Do what is right for the resource and the entire East Coast, not just one company and a handful of people driven by dollars and political donations. It is already going to take years for the ecosystem to recover above the bunker: whales, stripers, bluefish, osprey, tuna, on and on. We can do better.

Reduce the menhaden reduction industry take in the bay. More evenly distribute the percentage of the quota to provide the bait within the ecosystem when most needed.
The health of the bay and the many it supports, takes precedence over the few who are negatively exploiting the resource. Common sense, scientific management of the has been stymied for too long. The public is feed up and will no longer accept ineffective action.

As an avid bird watcher from Cape May, New Jersey, I have concerns about the decline in both the osprey and menhaden populations. I'd like to express my support for precautionary menhaden management as more data is gathered to inform the science and conservation actions. I believe catch limits should be put in place throughout the Atlantic coast and should take into consideration seasonal changes related to local osprey populations.

As a homeowner along the Eastern Branch of Carter's Creek in White Stone, VA, my wife and I have witnessed a steady decline in Ospreys successfully nesting in our area. This year there was only one successful nest near the mouth of the creek as it enters the Rappahannock, whereas in prior years there have been multiple successful nests at the mouth and scattered up the creek. We can only associate this decline with reduced food resources for the Osprey locally and so they are abandoning the area and not procreating. It is our understanding their primary food source is Menhaden and conclude they have become harder and harder for Ospreys to find in our area.

It is our wish that further reductions be made to commercial Menhaden catch limits so this important resource can recover and feed all of the wildlife populations that depend upon it. Thank you.

Please stop or set minimum menhaden harvest levels for entire Atlantic region. I've been boating and fishing in the Chesapeake Bay for for 45+ years and have witnessed the depletion of the menhaden population. In my observations the large schools of surface feeding menhaden normally seen in open bay waters disappeared around 2012. The schools of juvenile (popcorn) menhaden no longer visit my creek (Sue Creek MD).

It is imperative to protect menhaden as they are a key food source for many species of fish and of course the osprey. We can not sit back and watch as the osprey which has made an amazing recovery from being greatly endangered struggles greatly once again. The waters must be protected from fishing and pollution so populations of osprey and all the species which depend on bunker fish can survive. It is heartbreaking to see a species struggle to raise their young, who are destined to die of starvation. We can and must help. I support the Atlantic Menhaden Draft Addendum.

Watching osprey chicks starve in their nests is heartbreaking—and it should be a wake-up call. These birds depend on Atlantic menhaden/bunker, a small forage fish that supports the entire coastal food web, from ospreys and seabirds to larger fish and whales. When parents can't find enough food to bring back to their young, the problem is much bigger than one species. NJ needs real monitoring, accountability, and management that protects forage fish where wildlife actually needs them—not just numbers on paper. The shore's ecosystem is telling us something. We need to listen.

I am in favor of the greatest restriction possible for the reduction of overfishing of menhaden.
It is very apparent how important this fishery is for the health of the entire ecosystem.
Its not ljke these fish are feeding people! It makes no sense to allow over fishing to supply the supplement industry.
Please implement the greatest restriction possible!
The health of the entire Bay -- fish, birds, and the entire ecosystem is based on a healthy population of bottom of the food chain, menhaden.
Sincerely
Jim Curcio

Hello,

I am writing in support of Addendum II because it is critical that we preserve the health and sustainability of our local ecosystem. One of the best parts of living in the DMV is the biodiversity. My sons play soccer at a school where Ospreys nest each year. Sitting on the sidelines week after week, fellow parents and I had the privilege of watching the parents build their nest and return with food for their young. Many summers, my family and I have traveled to the eastern shore and spent hours observing the hard-working shorebirds search for food. Our local and migrating wildlife make our world richer. We must do what we can to preserve this beauty and the heath of our Chesapeake community for future generations before it is too late.

Thank you,

Alexandra Reams

I am writing as a concerned citizen to urge the Atlantic States Marine Fisheries Commission (ASMFC) to take decisive, precautionary action to protect our coastal ecosystem by enacting the maximum proposed protection measures under Draft Addendum II. Specifically, I strongly advocate for lowering the Chesapeake Bay industrial reduction fishery harvest cap by the full 50%, reducing it from the current 51,000 metric tons down to 25,500 metric tons.
As a cornerstone forage fish, Atlantic menhaden are vital to the health of the entire Atlantic ecosystem and the Chesapeake Bay nursery. They are a critical food source for economically and ecologically important predators, including striped bass, bluefish, osprey, cobia, and marine mammals.
Allowing massive industrial purse seine operations to concentrate their harvest inside the sensitive waters of the Chesapeake Bay creates localized depletion. The consequences of this are already visibly damaging our ecosystem, as evidenced by unprecedented osprey nesting failures due to food stress and struggling recreational and bait fisheries.
To protect the biodiversity of the Bay and support the broader coastal food web, I ask the Board to approve:
1. The full 50% reduction of the Chesapeake Bay Cap to 25,500 metric tons.
2. Seasonal quota periods to prevent intense, concentrated industrial fishing pressure during critical spring and summer months when wildlife and local watermen rely on menhaden the most.
3. A clear separation between the Bay Cap and the coastwide Total Allowable Catch (TAC) to ensure that conservation gains in the Bay are not undermined by quota reallocations.
Menhaden are worth far more left in the water as the foundation of our marine ecosystem than they are ground up for

industrial commodities. Please follow the ecological science and implement these necessary restrictions to safeguard the future of the Chesapeake Bay.
Thank you for your consideration on this critical matter.

Dear ASFMC Board and Officials:
Please implement the strictest caps possible on the menhaden fishery.
As a young lab tech in Maine's long term herring survey, former wife of a lobsterman, and sister to a marine biologist turned Maine Marine Patrol Officer, I have seen the pogie industry from a number of perspectives, most of them ruthless.

As prey, menhaden provide huge rewards for their predators, whether avian or human. They are fatty, oily, calorie rich, floaty, and heaven only knows, stinky. Though they are less profitable for pogie boats and processors, humans have lots of other options for these calories and oils. Fish-eating raptors, on the other hand, don't have the luxury of going to the supermarket for vitamins and protein powders. Data show them to be suffering severe population decline and Occam's Razor was never so sharp. The straight line goes directly to Omega Protein and its partner fishing fleet.

We learned in the 1960s with DDT how devastating removing raptors from our ecology could be. You can help prevent a repeat performance by reducing the menhaden fishing cap.

Thank you for your difficult work. I know firsthand how unhappy an unhappy fisherman can be.
Yours,

Leola Roberts
Alna, Maine

All the options assume we have accurate information as to the size of the population and the harvest numbers suggest we do not have a solid structure based on the number of menhaden being harvested. It isn't easy yet we must find ways to have more accurate counts so that the harvest numbers can be adjusted in real time. Adjusting the harvest numbers by votes and comments makes it so that the management is most likely to fail no matter how well the intention may be. As a key species to the overall health of the areas wildlife overshooting harvest numbers has a much greater impact than undershooting. Thank you for your time and attention in this matter it is a vital component to the overall well being,

The bay is dying at a fast rate! It's time to take drastic measures to save it! The recreational fishermen have had policies in places to cut their catches! It's time to cut commercial netting, including Omega to help bring the bay back from certain death! Cut the taking of menhaden at least 50% or move them off shore to the 3 mile limit like every other states on the east coast!

I support suboption B4- 50 % bay cap. Waiting for more scientific study in order to reach a definitive conclusion as to best management could delay action to a point of the ecological balance being thrown irrevocably into a downward spiral such that all species will suffer catastrophic depletion.
The initial fisheries management was a precautionary measurement. That philosophy needs to be continued. The longterm livelihood of all who would make their living from the harvesting of fish from the bays, tributaries and ocean on the Atlantic East Coast depend on wise management. Conservation of these natural resources are essential.

I support the strongest precautionary protections for Atlantic menhaden proposed in Draft Addendum II, including a 50% reduction in the Chesapeake Bay reduction-fishery cap and management measures that prevent concentrated harvest during critical periods for wildlife.

Atlantic menhaden are a foundational forage species that support ospreys and many other predators throughout the coastal ecosystem. The recent reproductive failures and food stress documented in osprey populations are deeply concerning. While there are still important questions about the causes of changes in local menhaden availability, that uncertainty is a reason to take a precautionary approach rather than wait for further ecosystem decline.

Please prioritize maintaining sufficient menhaden abundance and availability for the predators and ecosystems that depend on them. Protecting forage fish is not just about managing a single fishery it is about protecting the health and resilience of the entire coastal food web.

I am writing to strongly support the adoption of the following options under Draft Addendum II. These measures will reduce the Chesapeake Bay's menhaden reduction harvest, build a smarter, more precautionary management system, protect menhaden when and where they are most important, keep Bay harvest limits tied to coastwide management, and ensure that management can adapt as new science becomes available.
3.1 Chesapeake Bay Reduction Fishery Cap Amount: - I support option C1e, which would reduce the Bay Cap by 50 percent and limit it to 13.6 percent of the Coastwide Catch Limit (TAC). I also support option C2a, which sets an upper limit of 51,000mt for the Bay Cap — which is the current level.
3.2 Chesapeake Bay Cap Distribution: - I support option B2, which establishes three equal-length quota periods for the Bay Cap, but distributes harvest as follows: 25 percent in period 1, 25 percent in period 2, and 50 percent into period 3. I also support option B, which establishes quota-period overage payback and rollover of unused quota within a fishing year.
3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision: - I support option B Revisit Provision, which would reassess the efficacy of these new management tools every 3 years.
I appreciate the opportunity to comment on Draft Addendum II and strongly urge the adoption of the sections outlined above. Ospreys and hundreds of other bird species depend on healthy menhaden populations that are sustainably managed. This is best accomplished by adopting options 3.1, 3.2, and 3.3 in Draft Addendum II.

As I resident of Middlesex Va whose property is on the Rappahannock in Deltaville, I support suboption B4- full 50 percent bay cap

I've seen first hand from our dock the menhaden one day and ability to fish and literally the next several days the Omega boats sucking up everything and no more fish to be had.

They should not be in my backyard or the Bay where the menhaden spawn and given a chance to grow. All the osprey are gone and I've seen only a few dolphin one time. This is not what was here when we moved here 14 year's ago.

Please heed this. We are angry and sad watching what is happening.

Thank you.

In 2007 H Bruce Franklin wrote a book titled "THE MOST INPORTANT FISH IN THE SEA: MENHADEN AND AMERICA. Twenty years ago he could see the dangers of commercial overharvesting of this oily fish that has been targeted commercially for over one hundred years. Now multiple spotter planes work in conjunction with steel ships to encircle entire schools in one set. For too long our fishery managers have kicked the can down the road and failed to properly regulate these vital fish. They say we need more study. Then they will take years to agree on how the study should be conducted. The Menhaden are far fewer and smaller in size. I support an 50% reduction on the Total Allowable Catch by the reduction fishery in the Chesapeake Bay and not one phased in over multiple years. I fear if swift action is not taken now a total ban may become necessary in Virginia waters as many other states have done. Protect the resource before its too! late.

I am writing to express my strong support for Draft Addendum II to Amendment 3 of the Atlantic Menhaden Interstate Fishery Management Plan. It is critical that we take steps to protect the ecological health of the Chesapeake Bay and the many species that depend on menhaden as a primary food source.

I urge the commission to adopt a precautionary approach by reducing the Chesapeake Bay Reduction Fishery Cap by 50%. Additionally, implementing seasonal quota periods will help prevent large, concentrated harvests during the spring and summer months when predators like osprey and striped bass are most actively feeding.

Thank you for your consideration and for your continued efforts to manage this vital resource sustainably.

Hello, I am a resident of New Jersey and have spent a large portion of my life on/around the water of the northeast in both a recreational and professional setting. It doesn't take long to notice the impact resulting from poor management of natural areas, and when you bring data to back it up, we should immediately begin asking "how can we fix this?" One way is to further limit fishing and harvesting allowances, and another is to establish and broaden marine protected areas. It is imperative we spend more effort protecting the natural world.

Thank you.

Please do something about the massive fishing of Menhaden. What gives a company the right to fish in massive quantities to where it can deplete a food source necessary for the survival of The Osprey?
Rhode Island offers a registration plate with an Osprey on it and the words, " Conservation through Education! I would suggest more educational programs for fishing communities and companies who fish to deplete a food source that is needed for survival!

I strongly support stricter catch limits and protective measures for Atlantic menhaden. Often called the most important fish in the sea, menhaden are being over-concentrated and overharvested by industrial operations, starving local predators like striped bass and ospreys. New Jersey's vibrant recreational fishing and coastal economies rely on a balanced marine ecosystem. I urge management agencies to cut harvest caps significantly and prioritize ecological health over industrial reduction fishing. Thank you in advance for protecting this important natural resource.

I am against the commercialized overfishing of the Chesapeake Bay Area and surrounding estuaries. The Menhaden bunker fish population decline has severely affected the Osprey population on the Barnegat Bay here in NJ. The Osprey and eagles and other top predators need the bunker as a primary food source.

I have fished the middle and lower bay for 22 years. When cleaning Rockfish, they usually had 4,6,8” menhaden in various stages of digestion. Now they either have nothing in their digestive system or maybe a few shrimp. When boating in Maryland, the screen is full of bait fish, cross into Virginia and the screen goes bare. That’s enough science for me! Stop the gross over harvest in the bay. Let them fish offshore like every other state.

Dear Mr. Boyle and members of the Atlantic Menhaden Management Board,

I am a birder and conservationist from the Washington, DC area, and I am writing in support of strong, precautionary action in Draft Addendum II to protect Atlantic menhaden in Chesapeake Bay and the wildlife that depends on them, especially ospreys.

The Bay supports one of the largest concentrations of nesting ospreys in the world, and research has found that menhaden make up a large share of their diet. Studies by Dr. Bryan Watts / the Center for Conservation Biology, William & Mary University, menhaden availability to osprey nesting success. Ospreys are not included among the predator species in the ERP assessment, so the draft's discussion of forage needs does not capture them. I urge the Board to consider piscivorous birds like ospreys as it weighs the risk of reduced menhaden availability in the Bay.

The draft documents declining menhaden availability: a 60% drop in Maryland pound net harvest in 2024, declining pound net CPUE in Maryland, Virginia, and the Potomac, and a sharp decline in the Choptank River adult index that persisted into 2025. I recognize the uncertainty about true Bay abundance. But the Bay is a critical nursery area, and ospreys have only a short season to feed their chicks. That argues for caution.
3.1 Bay Cap Amount: Option C (Sub-Options C1d and C2b).

Linking the cap to the TAC is essential. The 2026 TAC cut left the cap unchanged, raising the share of reduction quota that can be taken in the Bay from 32% to 40%, the highest since 2017. I support C1d (a 30% reduction relative to the 2026 TAC) with C2b (upper limit of 51,000 mt, lower limit of 25,500 mt). This is precautionary but within the range the Board put out for comment.

3.2.1 Quota Periods: Option B2
Osprey chicks hatch and are fed through the summer. In 2023 and 2024, over 50% of Bay reduction landings came in a six-week mid-summer window, and historically 54% of landings fall between early July and mid-September. Option B2 best limits harvest during that critical period by holding it to 50% of the cap through mid-September.

3.2.2 Overages and Underages: Option B, with Underage Sub-Option 1
Payback provisions are needed for the quota periods to mean anything. Sub-Option 1 spreads Period 1 underages across the rest of the season.

3.3 Revisit Provision: Option B

A three-year revisit lets the Board act on new science, including research toward a science-based Bay Cap.

Thank you for considering my comments.

Every other state on the eastern seaboard has pushed the reduction fishery out of state waters just because it's been done for "100 years" doesn't mean it doesn't and is not having a negative impact on our ecosystem, I've grown up my 45 years on the lower Chesapeake bay and have never seen such a lack of menhaden, if the bay population was healthy the reduction fleet wouldn't be traveling up to NY/NJ as well the lack in menhaden could probably be tied to the low crab counts as predators are going to eat or they won't stay when there no food so before our recreational and charter fisheries collapse please do your part in protecting our fisheries that feed our communities not just one foreign company

Mark Robichaux in his well read article that "Virginia is the only state left on the East Coast that allows this “reduction” seining of menhaden." Omega Protein, a subsidiary of Canada-based Cooke Inc., operates the Atlantic coast’s largest commercial fishery. This company has used the Osprey decline documentation to disprove the science as inadequate. Due to Virginia's house & senate inaction, the status que remains.
I understand and hope to be wrong, that Virginia's legislature does not meet till 2027.
Either way, the Atlantic Menhaden Management Board cannot implement the Menhaden Draft unless Virginia law can change.
Since Virginia has done nothing all these years, why expect anything else ?

My name is Chuck Dishian and I represent the Village Harbour Fishing Club. The club includes over 150 members and is an arm of the Jersey Coast Anglers Association. With regard to the Atlantic Menhaden Draft Addendum II, teh VHFC supports the following:

• Bay Cap Amount: Sub Option B4 — a 50% reduction, resulting in a 25,500 mt cap.
• Quota Periods: Option B1 — even length periods with evenly distributed harvest.
• Underage Provision: Underage Sub Option 1 — roll Period 1 underages evenly into Periods 2 and 3.
• Revisit Provision: Option B — revisit the Bay Cap every three years.

Thank you for your kind attention.

Writing to support the Chesapeake Bay Cap Draft Addendum II related to reduction of menhaden removal, as well as the time restriction to be applied to the quota. The reduction fishing industry is simply not sustainable in the modern era, and in the end ASMFC and the industry itself must control the removal of forage or the entire fishing AND reduction industry will eventually collapse. To delay more significant regulation further is a short sighted approach that does not benefit ANY of the parties involved long term.

Good morning, I fish recreationally in Connecticut and Rhode Island and over the past ten years the average weight of the striped bass I have caught has gone down. They appear slimmer than in the past and while this is only anecdotal I would support the reduction of the menhaden commercial fishery to support a larger biomass target. ASMFC seems to use the striped bass as a bell weather for the fishery balance but many other populations also use menhaden as a food source. There have been recent published articles about ospreys having difficulty providing enough food for their offspring. In Eastern Long Island Sound and in Block Island Sound we rarely see menhaden. I support a reduction in the Atlantic Menhaden fishery. Thank you. John Grady

Subject: Public Comment: Atlantic Menhaden Draft Addendum II

To: comments@asmfc.org

Dear Mr. Boyle and Members of the Commission,

I am writing to urge the Atlantic States Marine Fisheries Commission to take immediate, strong action to protect the Chesapeake Bay ecosystem by implementing strict catch limits under Atlantic Menhaden Draft Addendum II. Specifically, I support options that substantially lower the reduction fishing allowance in the Bay.

As a resident/supporter of the Chesapeake Bay region, I am deeply alarmed by the unprecedented breeding failures and starvation currently devastating our local osprey populations. Decades of scientific monitoring show a direct link between the lack of mature Atlantic menhaden and the inability of ospreys to successfully raise their chicks.

Menhaden are the ecological backbone of the Chesapeake Bay. Allowing industrial-scale reduction fishing to deplete this critical forage fish at the expense of ospreys, striped bass, and other native wildlife is unsustainable and unacceptable.

Please prioritize the long-term health of the Bay's ecosystem over short-term commercial harvest by implementing the maximum possible protections in Draft Addendum II. Thank you for your time and consideration of these comments.

Sincerely,

Terrence Moran
Stevensville, Maryland

Watching the recovery of our raptors over these last few decades has given me some faith in our ability to coexist with the other species that live on this earth with us. It's devastating to see the reports of starving osprey chicks when in recent years they were thriving. Although there could be many factors contributing to this loss, the menhaden depletions seems to be a major issue, signaling a serious imbalance in the local ecosystem. When such a large food source changes it's population, many ecological systems fail, and the osprey is one of the bellwethers. This must be addressed immediately to restore the natural system, not only for the wildlife that depends on them, but for us as well. Please do everything you can to support the Atlantic Menhaden Draft Addendum II.

When the ecosystem is showing signs of impact, you must act now as it will already take time to reverse the damage. Just as the damage has been mounting and we didn't see it immediately; if we wait, we cannot foresee its long term damage which will no doubt have a ripple effect throughout the ecosystem and more species will become under threat or worse extinction. STOP OVER FISHING NOW, THERE IS TOO MUCH AT STAKE!! I have family that live near the Chesapeake and this is extremely upsetting news.

Atlantic Menhaden serve as a vital source of food for many keystone species such as ospreys, dolphins, and whales. When I visit the Chesapeake Bay with family, I always look forward to seeing the osprey nesting and hunting for their chicks. They are one of my favorite birds to photograph. Currently, ospreys are struggling to feed themselves and their chicks due to lack of food. By reducing the harvest of Atlantic Menhaden, we can protect ospreys and other vital species from starvation.

I am writing to ask you to initiate rulemaking establishing a twelve nautical mile buffer along the entire Atlantic coast in which industrial menhaden reduction vessels may not fish, year-round.

Atlantic menhaden has no federal fishery management plan. That absence is the express trigger in the Atlantic Coastal Fisheries Cooperative Management Act. Section 804(b), 16 U.S.C. 5103(b), authorizes the Secretary of Commerce to implement regulations in the exclusive economic zone where no Magnuson-Stevens plan exists. NOAA has used that authority before; the resulting rules sit at 50 CFR Part 697 and cover weakfish, red drum, American lobster, and horseshoe crab.

In October 2025 the Atlantic States Marine Fisheries Commission cut the 2026 coastwide catch limit by 20 percent, to 186,840 metric tons. Landings in 2024 were 186,155 metric tons. The new limit sits roughly four tenths of one percent below what the fishery had already caught.

By the Commission's own 2025 assessment, fishing mortality in 2023 ran at 1.69 times the ecological target and egg production stood at 71 percent of its target.

A 2026 study of 571 osprey nests in the Chesapeake Bay found that in menhaden-dependent waters, pairs raised 0.51 young

against a replacement rate of 1.15. Thirty miles away in the same bay, where other prey remains available, the same birds produced 1.36. The chicks hatch, and then they starve in the nest.

Ten Atlantic states, from New Hampshire to Florida, already prohibit purse-seining for menhaden, or prohibit it specifically for reduction, within their own waters. Those states acted to the full extent of their jurisdiction, which reaches three nautical miles. Only federal action can carry that principle further offshore.

I am not asking you to end this fishery. I am asking you to move it away from the shoreline, where the birds, the whales, and the gamefish that support coastal economies actually feed, and to do so before the Commission meets in November.

Please initiate rulemaking under section 804(b).

Please reduce the amount of menhaden allowed to be harvested. This year due to severe shortage on jfmgaddn in southern nj, Osprey nests (such as those in Forsythe National Wildlife Preserve as documented by Conserve Wildlife NJ and personally witnessed by me) did not produce hardly any offspring because there wasn't enough food.

I'd prefer if you shut down the commercial harvest completely. Because as everyone knows, menhaden are the most important fish in the sea, they are the primary food source for many other fish and cetaceans.

Sincerely and respectfully,

William Harclerode

While visiting Avalon, NJ, I noticed we did not see as many osprey as we did in previous years. I understand the nests have not been successful this year, and the osprey are not able to produce offspring or even survive due to the declining numbers of Atlantic menhaden. Please stop the overfishing of the menhaden by reducing the fishery cap by 50%. I feel this is imperitive to ensure the survival of the osprey.

This overfishing problem needs immediate attention and I strongly suggest that you tighten fishing limits as much as possible. If further studies suggest that overfishing is not the problem with the Menhaden decline the limits can be elevated back to safe levels after the studies are completed.

As a surf fisherman of over 30 years I have seen menhaden all but disappear from the coast in the past few years in Monmouth County, NJ. Tackle shops can't get them, charter boat fishermen can't find them. And worst of all, sea birds like osprey are dying and starving. Please pause commercial and reduction fishing if this important forage fish.

Comment

To the Atlantic States Marine Fisheries Commission:

I am submitting this comment in support of the strongest available protections for Atlantic menhaden under Draft Addendum II, including the maximum 50% reduction in the Chesapeake Bay reduction fishery cap and measures that prevent industrial harvest from being concentrated during critical periods of the year.

Menhaden are not simply another commercial fish stock. They are the foundation of the coastal food web from Virginia through Delaware, New Jersey, New York and beyond. Striped bass, bluefish, weakfish, tuna, marine mammals, ospreys, eagles and countless other predators depend on them. Managing menhaden only by asking whether the coastwide stock is technically “overfished” misses the larger ecological issue: whether enough menhaden are available, in the right places and at the right times, to support the ecosystem that depends on them.

The situation in the Chesapeake Bay should be a warning that the current approach is not sufficiently precautionary. ASMFC itself has acknowledged concerns about declining pound-net harvest and catch per unit effort in the Bay, the increasing concentration of reduction harvest during the summer, and possible downstream effects on menhaden predators.

At the same time, researchers are documenting alarming reproductive failure among Chesapeake Bay ospreys associated

with food limitation and inadequate availability of menhaden. Ospreys recovered from the devastating effects of DDT only to now face another completely avoidable threat: an insufficient supply of their primary prey in portions of one of the most important estuaries on the Atlantic Coast.

It is difficult to justify allowing an industrial reduction fishery to remove enormous quantities of one of the ecosystem's most important forage species from the Chesapeake Bay while predators are struggling to find enough food to successfully reproduce.

Omega Protein's reduction fishery does not exist in isolation. What happens in the Chesapeake affects a connected Mid-Atlantic ecosystem. Menhaden migrate along the coast and support recreational fisheries throughout Virginia, Delaware, New Jersey and New York. Recreational anglers throughout this region understand something that management models can sometimes obscure: abundant forage is what creates healthy fisheries.

Menhaden have far greater value in the water supporting striped bass, bluefish, tuna, weakfish, marine mammals and birds than they do after being reduced into fish meal and fish oil.

I recognize that ASMFC's current stock assessment classifies Atlantic menhaden as not overfished and states that overfishing is not occurring. But a coastwide stock assessment cannot by itself answer the question of localized depletion. A species can be healthy on a coastwide statistical basis while predators and fishermen in particular areas experience severe shortages of forage.

That is exactly why the Chesapeake Bay cap was created in the first place.

The Commission should apply the precautionary principle rather than waiting for absolute scientific certainty after ecological damage has already occurred. When osprey chicks are starving, fishermen are reporting changes in forage availability, Bay catch rates are declining, and industrial harvest is increasingly concentrated in particular seasons and locations, the responsible management response is to leave more menhaden in the water.

I therefore strongly support:

• The maximum 50% reduction in the Chesapeake Bay reduction fishery cap.

• Seasonal quota periods that prevent the reduction fleet from concentrating a large portion of its harvest during periods when menhaden are critically important to predators.

• Continued development of management measures that account for localized depletion rather than relying exclusively on coastwide abundance.

• Greater consideration of the needs of ospreys, striped bass and other predators when determining how many menhaden can safely be removed.

• Long-term movement toward managing menhaden first and foremost as an essential forage species supporting the entire Atlantic coastal ecosystem.

ASMFC has an opportunity with Draft Addendum II to demonstrate that ecosystem-based fisheries management means more than simply keeping a forage species above an overfished threshold.

There must also be enough menhaden left in the water to perform the ecological role that makes this species so important.

Please choose the strongest conservation measures available under Draft Addendum II and significantly reduce industrial reduction harvest in Chesapeake Bay.

The health of the Chesapeake Bay and the recreational fisheries of Virginia, Delaware, New Jersey, New York and the rest of the Atlantic Coast depend on abundant forage.

Menhaden belong in the food web.

A concerned lifelong NJ Waterman,
Shaun N. Strain

On the ground in coastal New Jersey, we have observed a marked increase in food stress over recent years, when adult ospreys cannot find enough prey to sustain their brood.

This isn't new. In the mid-1950s, Herbert Mills, founder of The Wetlands Institute, noted that menhaden were commonplace. By the mid-1960s, offshore trawling coincided with the disappearance of menhaden and osprey declines. Population crashes led to them being listed as endangered in 1974.

In 1997, a New York Times headline warned “Ospreys May Be Starving” as coastal colonies failed. In response, New Jersey passed a landmark 2002 bill banning the industrial harvest of menhaden from state waters to prevent localized overfishing and protect coastal ecosystems.

This year at Sedge Island, home to New Jersey’s most densely populated colony, only two young fledged (down from a normal average of 40). Food stress was widespread across all coastal colonies. In spring, many females did not lay eggs due to lack of prey. Males spent more time away foraging, leaving females starving and forced to forage themselves, leaving young vulnerable to predators and exposure. Chicks grew emaciated and starved.

In 2025 and 2026, an average of 51% of active osprey nests failed, more than double the previous decade's average rate.

Brood sizes are dropping: only 5% of pairs produced three young in 2025–26, compared to a ten-year average of 22%.

This humble forage fish fuels predatory fish and sustains top predators like eagles, ospreys, tuna, striped bass, dolphins, and whales.

these are the words of Ben Wurst who devoted his career to observing and protecting these special birds. I believe we can do much better to give them a chance and to bring back so many species and protect rebuilt the Atlantic coast

I support the draft addendum, which is necessary to deal with local menhaden depletion
which is affecting our nesting ospreys along with likely other species not as easily studied. It is critical to approve this measure of precautionary management for avian species along the east coast.

i steward 4 osprey nests in Clinton CT. Last year 5 ospreys fledged. This year only 1. I kayak down the Indian river into LI Sound and this year did not see any schools of fish in June, July and August, just when the need is high for osprey food. In speaking to local fishermen, they stated that they were unable to get bunker from their local bait shops. Please hear my plea! These birds are magnificant. We let mthem survive from DDT; let them survive again....STOP THE OVERFISHING OF MENHADEN!!!!!

I am writing because I am deeply concerned about the continued large-scale harvesting of menhaden from the Chesapeake Bay. As someone who cares deeply about birds, wildlife, and the health of our natural places, I find it incredibly troubling that we continue to remove enormous numbers of such an important forage fish without fully understanding what we may be doing to the larger ecosystem.

My concern goes far beyond menhaden themselves. These fish are part of an interconnected food web that supports ospreys and many other species. Watching an osprey hunt, carry a fish back to its nest, and raise its young is one of the experiences that makes the Chesapeake Bay such a special place. The possibility that we could be contributing to the decline of these birds by removing too much of their food source is heartbreaking—and should be taken very seriously.

What concerns me just as much is what we don't yet know. We have a long history of learning too late that removing one species or altering one part of an ecosystem can have consequences that ripple outward in ways we never anticipated. We should not have to watch osprey populations or other wildlife decline dramatically before deciding that perhaps we have taken too much.

The Chesapeake Bay already faces enormous pressures from pollution, habitat loss, warming waters, and climate change. Why would we knowingly place additional pressure on its food web by allowing intensive commercial harvest of a species that

so many other animals depend upon?

I believe we have an obligation to err on the side of protecting this extraordinary ecosystem. Menhaden should be managed not simply as a commodity to be harvested, but as a critical part of a living Chesapeake Bay.

Please significantly reduce industrial menhaden harvest within the Bay and put the health of the Chesapeake ecosystem first. Once an ecosystem is damaged, restoring it can take generations—if restoration is even possible. We should not look back years from now and wish we had acted when we still had the opportunity.

Dear Fisheries Managers:

As a lifelong fisherman on the Chesapeake Bay and along the Atlantic Coast, I feel strongly that Addendum II needs to give Menhaden a fighting chance to avoid overfishing and best support the coastal economies of this country, its wildlife, and all user groups (not only commercial fishermen).

In the Chesapeake Bay, I have, in my lifetime, seen a diminishment of the total number of adult menhaden schools encountered when fishing the middle and lower bay (primarily over the last decade), and simultaneously seen a sudden decrease in nesting Osprey pairs in my home Virginia creek (Hungars). It is extremely alarming, and the best available science supports the decrease in menhaden abundance as a key driver in the success of osprey reduction. I am praying our fisheries managers (you/your colleagues) use the best available science to make decisions in the best interest of the resource.

As for the Chesapeake Bay Cap, I strongly support the following:

Section 3.1: Sub-Option B4 (50% reduction in the current bay cap).
Section 3.2.1: Underage Sub Option 1 (An underage in Quota Period 1 would be split evenly and rolled over to Quota Period 2 and 3)

Section 3.3: Option B (A review of the Chesapeake Bay Cap will occur at minimum once every 3 years)

Thank you for your time and your service. You and your team are stewards of an incredible resource, and with that comes a heavy responsibility to the resource. I wish you success in your analysis and ultimately the decisions that will affect these fish, people, and wildlife of the Chesapeake Bay for years to come.

Regards,
Matthew Roach
Hungars Creek, Virginia

For the past 5 years I've seen less and less menhaden in the waters I fish and this year could be the worst yet almost no schools of adult menhaden to be found in places they show up year after year consistently. The juvenile menhaden population also appears to be lacking with multiple estuaries that in years past were loaded with them now have absolutely zero. I believe the quota for commercial fleets up and down the east coast should be reduced or maybe even make them stop all operations for 1 to 2 years to allow the population to rebuild. The menhaden are extremely important for all species including birds, fish and mammals and I believe continuing down the path we are now could lead to a complete collapse of menhaden populations which will directly affect species like striped bass, humpback whales and osprey.

Dear members, please consider the interest of the greater good when making decisions that will impact our generation and future generations. Please end or significantly scale back the menhaden reduction fishery. It makes no sense to allow a foreign owned entity to pillage the forage fish in our American waters for profit. This has been shown by the science to harm not just the fishery of striped bass, bluefish, red drum but also ospreys, birds and sea mammals. Please protect our environment for us current stakeholders and our children.

We have watched the osprey nest 60' from our shoreline for 30 years. At the beginning we had 2-3 babies fly away successfully. Then it became less and less. For the past 4 years, the same osprey couple have conceived, laid eggs, but nothing hatched. We used to see them dive for meals in our little bay. We think the increasing turbidity has made it very difficult to see the perch food and, therefore, no longer fished in our little bay. Having to fly about 2-3 miles to the mouth of Island Ck, the osprey returned with their food. The past 2 years, our nest was one of two nest platforms on our Ck that had osprey residents. We counted at least 10 empty platforms for the past 2-3 years. Our conclusion is the water transparency has diminished AND there is no food close by. Fewer and fewer osprey arrive here in the spring. I imagine none will come next year.

The waning abilities of the Chesapeake ospreys to be able to produce full broods that make it to adulthood appears to be dropping year over year. We know that ocean temperatures have been a problem for several years and have been the worst on record this year. We also know, through decades proving as such, that the disappearance of predators from different food webs can cause large scale problems, though those issues arise slowly until it's too late to walk back the original issues. Let's stay ahead of this one and leave more fish for the other animals in the ecosystem who need it before other issues arise because we got too greedy.

Atlantic States Marine Fisheries Commission Seeks Your Input on
Atlantic Menhaden Management
The public is encouraged to submit comments regarding this document during the public comment period. Comments will be accepted until 11:59 p.m. EST on October 9, 2026. Regardless of when they were sent, comments received after that time will not be included in the official record.
We accept public comment in several forms (at public hearings, an online public comment form, an online public comment survey, and via mail or email) and all forms are equally valued. However, we strongly encourage the use of the public comment survey as it allows users to

select specific preferred options in the Draft Addendum and provides space for open-ended comments at the end.

1. Attend public hearings pertinent to your state or jurisdiction (see Action Tracker page for hearing schedule).
2. Online via the public comment survey
3. Online via comment box
4. 5. Email: comments@asmfc.org (subject line: Atlantic Menhaden Draft Addendum II)

Mail: James Boyle, ASMFC, 1050 N, Highland Street, Suite 200-N, Arlington, VA 22201

If you have any questions please contact James Boyle at jboyle@asmfc.org or 703.842.0740.

TBD Provisions of Addendum II are Implemented

1. INTRODUCTION

The Atlantic States Marine Fisheries Commission (ASMFC) coordinates Atlantic menhaden (Brevoortia tyrannus) management in state waters (0–3 miles from shore) under the authority of the Atlantic Coastal Fisheries Cooperative Management Act and has done so through an Interstate Fishery Management Plan (FMP) since 1981. The states of Maine through Florida have a declared interest in the fishery and are responsible for implementing management measures consistent with the FMP. For the purposes of this draft addendum, the term "state" or "states" also includes the Potomac River Fisheries Commission (PRFC). Management authority in the Exclusive Economic Zone (3-200 miles from shore) lies with NOAA Fisheries.

At its October 2025 meeting, the ASMFC's Atlantic Menhaden Management Board (Board) approved the following motion:

Move to initiate Addendum II to the Atlantic Menhaden FMP to address Chesapeake Bay management concerns. The addendum shall develop periods for the Chesapeake Bay Cap that distributes fishing effort more evenly throughout the season and a range of options to reduce the Bay Cap from status quo up to 50%.

Since then, the Board has provided additional guidance on the purpose and range of options for inclusion in this draft addendum.

2. OVERVIEW

2.1 Statement of the Problem

The availability of menhaden in Chesapeake Bay may be affected by changes in total abundance, size distribution of the population, and timing of spatial distribution in the Bay, which can be caused by fishing pressure, environmental conditions, habitat suitability, and/or changing predation pressures on a limited spatial and temporal scale. Such changes in menhaden availability may affect the species' ability to fulfill its ecological and/or economic functions. Recent observations of below average commercial fisheries landings and concerning population trends in several species that use menhaden as prey within Chesapeake Bay suggest that availability of menhaden in Chesapeake Bay may be changing due to one or more of the above drivers. Of the predator species included in the ecological reference point (ERP) assessment, which accounts for menhaden's role as a forage fish, the latest coastwide assessments indicate striped bass is overfished, bluefish are presently rebuilding, weakfish are depleted due to high levels of natural mortality, and spiny dogfish reproductive output is declining but stabilizing (ASMFC, 2024).

Although there are currently not sufficient scientific data available to comprehensively characterize the abundance and distribution of menhaden throughout Chesapeake Bay and the influence of fishing pressure on menhaden, the Commission has been using proactive measures to manage this species in the face of uncertainty and to support both ecological and fishery objectives. Specifically, since 2006, the Chesapeake Bay Reduction Fishery Cap (Bay Cap) has limited harvest of menhaden by the reduction fishery (henceforth, "reduction harvest") within

Chesapeake Bay. This draft addendum responds to concerns that the Bay Cap does not control how harvest is distributed throughout the fishing season and that the amount of the Bay Cap

does not reflect changes to the coastwide total allowable catch (TAC).

Chesapeake Bay Reduction Fishery Cap

The first issue addressed in the draft addendum is that the Bay Cap is not linked to the overall TAC. Large changes to the TAC without a corresponding change to the Bay Cap significantly alter the percent of the reduction landings (and total landings) that can be taken from Chesapeake Bay, a critical nursery area for menhaden. For example, because Virginia is currently allocated 75.21% of the coastwide TAC, and Virginia allocates 90.04% of their quota to the reduction sector, the current Bay Cap (51,000 mt) paired with a 100,000 mt TAC would allow 75% of the reduction fishery quota to be taken in Chesapeake Bay, but with a 300,000 mt TAC would allow 25% of the reduction fishery quota to be taken in Chesapeake Bay. Such variable outcomes may be inconsistent with the intent of the Bay Cap. The 20% reduction applied to the TAC in 2026, without a corresponding change to the Bay Cap, increased the percentage of possible reduction fishery quota taken in the Chesapeake Bay from 32% to 40%, a larger percentage than has been possible since 2017. The Board is concerned that without a change to the Bay Cap, future changes to the TAC could further shift that percentage. Additionally, changes to the Bay Cap can only be made through an amendment or addendum, meaning the Management Board is often unable to align the timeline for changes to the Bay Cap, if desired, with changes to the TAC. Therefore, this draft addendum considers a one-time reduction in the Bay Cap in consideration of recent or upcoming changes to the TAC and setting the Bay Cap as a proportion of the TAC so that it changes automatically with future changes to the TAC.

Timing of Menhaden Harvest

The second issue this draft addendum aims to address is that the Bay Cap is an annual measure without any associated controls on how reduction harvest is distributed throughout the fishing season. This leaves the potential for a concentration of reduction fishery landings in a short time period, as seen in 2023 and 2024, when over 50% of the Bay reduction fishery landings were taken in a 6-week period in mid-summer. When this occurs, it is possible that these higher-than-normal catch rates could affect availability of menhaden to other fisheries or predators, which is what the Bay Cap was intended to prevent. Consequently, this draft addendum considers establishing quota periods for the Bay Cap to redistribute reduction fishery landings across the reduction fishery season, rather than concentrating them in the beginning and middle of the season.

Revisiting the Bay Cap

Lastly, given the breadth of changes proposed to the Bay Cap in this draft addendum, the uncertainties about whether recent trends in Chesapeake Bay menhaden landings and availability will continue, plus planned research intended to help design a scientifically-based Bay Cap setting process, this draft addendum includes an option that would require a revisit of the Bay Cap provisions every three years at a minimum. Currently, there is no set timeframe for revisiting the Bay Cap.

2.2.1 The Reduction Fishery
2.2 Background

Draft Document for Public Comment

Since 2013, total reduction fishery landings have been determined by the annual coastwide Total Allowable Catch (TAC) specified by the Management Board, the percent of the TAC allocated to Virginia by the Interstate FMP, Virginia's internal allocation of its quota among its fishery sectors, and the Virginia reduction fishery's performance with regards to its quota. Currently, Virginia's allocation of the TAC is 75.21%1 based on landings from 2018, 2019, and 2021, and the purse seine reduction fishery's allocation of the Virginia quota is 90.04% based on 2002-2011 average landings. Accordingly, the Virginia reduction fishery has the potential to harvest 67.04% of the TAC.

Reduction fishery vessel effort occurs both inside Chesapeake Bay and outside in the Atlantic Ocean. In the last five years (2021-2025), about 50% of all reduction fishery effort (i.e., purse seine net sets) has occurred within Chesapeake Bay, down from about 70% in 2009. The Bay Cap prohibits additional reduction harvest within the Chesapeake Bay when 100% of the Bay Cap is harvested from Chesapeake Bay, which is defined as areas shoreward of the Chesapeake Bay Bridge Tunnel.

Figure 2. Proportion of Virginia purse seine reduction effort in Chesapeake Bay.

2.2.2 Bay Cap History

The Chesapeake Bay Reduction Fishery Cap was first established in 2006 as a precautionary measure in response to an increasing proportion of the total reduction fishery landings being harvested from Chesapeake Bay and concerns about the possibility of localized depletion. Through Addendum III to Amendment 1, the Bay Cap was set at the average landings from 2001-2005 (109,020 mt) to prevent the expansion of the reduction fishery in Chesapeake Bay while the necessary scientific studies were conducted to explore the potential for localized depletion and set a more scientifically quantified harvest threshold if needed. Additional Bay Cap management measures included mandatory payback of any overage in the subsequent year and an allowance to rollover unused quota to the following year up to a specified

1 The state-by-state allocations exclude 1% of the TAC that is reserved for the Episodic Event Set-aside.

maximum. Notably, the adoption of the Bay Cap preceded the adoption of a coastwide TAC for menhaden, which did not occur until 2013 through Amendment 2.

Amendment 2 reduced the Bay Cap by 20% to 87,216 mt beginning in 2013. This 20% reduction mirrored the 20% reduction applied to the average coastwide catch from 2009-2011 that was used to set the first-ever TAC. (This was an ad hoc approach to set the TAC based on recent landings due to uncertainty in the 2012 stock assessment's projections; all subsequent TACs have been set using a stock assessment-based projection methodology). Amendment 2 also reduced the Bay Cap underage rollover maximum by 20%.

The next change to the Bay Cap occurred in 2018, when it was reduced to 51,000 mt in Amendment 3. Similar to how the Bay Cap was initially set, this amount represented an approximation of the average Bay reduction fishery landings from 2012-2016. This action again capped landings at recent levels as a precautionary management approach. Unlike the change to the Bay Cap in Amendment 2, this ~41.5% reduction in the Bay Cap did not correspond to the change made to the TAC in the same year (8% increase). Amendment 3 also removed the allowance for any rollover of unused Bay Cap (as well as any unused TAC) and established that unused quota from a region or state cannot be transferred to the Bay Cap to reduce an overage.

The Bay Cap has remained at 51,000 mt since 2018 (except in 2020 when it was reduced to account for an overage in 2019; reduction fishery landings from the Chesapeake Bay have always otherwise been below the Bay Cap). Since that time, the TAC has been adjusted three times, including a 10% reduction in 2021, a 20.1% increase in 2023, and a 20% reduction in 2026, all without any change to the Bay Cap (Table 1).

The history, intent, and setting process for the Bay Cap and TAC differ in notable ways. First, the Management Board sets the TAC through Board action based on coastwide stock assessment projections in comparison to target and threshold reference points. Since 2021, ecosystem-based stock assessments and reference points have been used, meaning the TAC is set to account for menhaden's role as a critical forage species on a coastwide basis. No similar approach exists to set the Bay Cap at a level scientifically determined to support forage needs in Chesapeake Bay; rather, recent landing levels have typically been used to set the Bay Cap, thereby preventing further expansion. Second, the TAC limits the total removals of menhaden coastwide by all fishery participants, in contrast to the Bap Cap, which limits only reduction fishery landings in Chesapeake Bay. Additional reduction harvest can take place outside of Chesapeake Bay, and additional bait harvest can take place inside of Chesapeake Bay. Third, the Bay Cap management measures can only be revised through an addendum or amendment to the FMP, whereas the TAC can be set by the Board through specifications (i.e., a Board vote) on an annual or multi-year basis. The result is that the TAC has changed with greater frequency, and changes to TAC and Bay Cap that do co-occur have not always been in the same direction.

Consequently, the amount of the Bay Cap as a proportion of the total TAC is variable over time (Table 1).

Table 1. History of coastwide TACs and Bay Caps.

Year	TAC (mt)	Bay Cap (mt)	Bay Cap as Percent of TAC
2006	-	109,020	-
2007	-	109,020	-

*2020 Bay Cap was reduced from 51,000 mt due to 2019 overage.

2.2.3 Seasonality of Chesapeake Bay Reduction Fishery

By Virginia law, the Chesapeake Bay purse seine reduction fishery is permitted to begin on the first Monday in May and ends on the third Friday in November. However, realized effort is based on resource availability as informed by the use of spotter aircraft to locate schools of menhaden. Consequently, the onset and magnitude of effort by week of the year is variable across years (Figure 3) as is the trend in cumulative percent of annual landings (Figure 4). For example, 2018 saw heavier effort and a steeper rate of landings earlier in the season than the years following; whereas 2023 and 2024 experienced delayed season starts but higher mid-season rates of landing compared to the years prior.

Figure 3. Percent of annual effort (number of net sets) by week for the menhaden purse seine reduction fishery in the Chesapeake Bay 2018-2024.

Figure 4. Cumulative percent of annual landings in the Chesapeake Bay menhaden reduction fishery 2028-2024.

2.2.4 Chesapeake Bay Pound Net Catch

The shift in Chesapeake Bay reduction fishery harvest later in the season in 2023 and 2024 corresponded with declines in Chesapeake Bay pound net fishery harvest (Figure 5), which typically peak during the summer months. For example, the Maryland Chesapeake Bay pound net harvest declined by 60% in 2024 from the 2018-2022 average. This co-occurrence raised concerns among Chesapeake Bay pound net harvesters, about a potential user group conflict with the reduction fishery and about an overall trend towards reduced menhaden presence, spatial distribution, and abundance within the Bay.

Figure 5. Total menhaden harvest in Maryland, PRFC, and Virginia pound net fisheries, 2018-2024.

The Plan Development Team (PDT) and Technical Committee (TC) investigated variability in fishery effort and/or menhaden availability as potential causes for the decline in pound net harvest. While true abundance (or availability) is not known, catch per unit effort (CPUE) can be used as a proxy if it is assumed there are no major changes to how the fishery operated between years.

Overall, the TC found notable declines in CPUE in the pound net fisheries of Maryland, Virginia, and PRFC in 2024 (Figure 6). As harvest declined, PRFC found a slight increasing trend in the time it takes to reach 50% of the annual cumulative harvest where 2024 was approximately 7

weeks later than the 2018-2023 average. PRFC and Maryland also discovered that the number of trips that caught 5,000 pounds or more of menhaden have declined to their lowest levels since 2018.

Figure 6. Annual menhaden Pound Net CPUE from Maryland, Potomac River, and Virginia. CPUE is in pounds per net day. Sources: Maryland DNR, PRFC, and VMRC.
Looking more closely at Maryland, during the second half of the year (weeks 27+), weekly CPUE in 2023 is generally equal to or greater than the 2018-2022 average (Figure 7), suggesting little influence of the reduction fishery on pound net catches. However, weekly pound net CPUE in 2024 shows a different pattern. Beginning in week 31 and continuing through the end of the year, CPUE in 2024 is generally below the 2018-2022 average (Figure 7). Just prior to this time period, the reduction fishery was experiencing higher than normal catch rates (Figure 8). The reduction fishery began in week 23, approximately five weeks later than 2018-2022, but by

week 33 had caught approximately 60% of the annual catch, which is in line with earlier years. It is possible that these higher than normal catch rates may have affected availability of fish in the upper bay, thereby affecting pound net catches. Although catch rates were higher than normal, total catch was equivalent among years. Any link between reduction harvest and availability in the upper bay would be a joint function of fishery dynamics and migratory patterns (e.g. timing and location) at a finer scale than could be considered in the PDT analysis.
Figure 7. Weekly CPUE in MD pound net fishery for weeks 27-52.
Figure 8. Timing of the Chesapeake Bay reduction fishery showing a delayed start with higher than average catch rates in weeks 23-33 in 2023-2024.
The PDT notes that the effort values used to calculate CPUE for all three pound net jurisdictions only includes nets catching menhaden. Menhaden account for a high proportion of some pound net harvesters' catch, which could lead to reduced effort if menhaden availability dropped to a

point where fishing was no longer profitable. Nets that remain profitable catching other species, but that no longer are catching menhaden would also not be included in the effort used in these calculations. These two factors could lead to more stability in the pound net CPUE as menhaden abundance declines, since only nets set in the best location to catch menhaden would be included in the effort used to calculate CPUE during a reduction in menhaden availability.

2.2.5 Chesapeake Bay Adult Fishery Independent Indices

The TC also looked at recent fishery independent indices included in the 2025 stock assessment for a trend in relative abundance, although noted that 2023 was the most recent year available in the assessment and that temporal and spatial differences between the surveys and fisheries make it difficult to compare the different trends.
For more recent data, the PDT reviewed the adult index from the fishery independent survey conducted in the Choptank River in Maryland (Figure 9). The survey has been conducted by Maryland DNR using gillnet gear during June-August since 2013. Between 2018 and 2023, the abundance appears to have been relatively stable with moderate interannual variability. In 2024, abundance dropped dramatically and remained low in 2025. While limited to a single tidal river system, the index does indicate lower relative abundance of adult Atlantic menhaden in 2024, as also indicated by the fishery dependent Pound Net CPUEs.
Figure 9. Maryland DNR Choptank River Gillnet Survey geometric mean catch per gill net hour and 95% confidence limits, 2013-2025.

2.3 Social and Economic Impacts

This Addendum includes measures that could influence the size of the Chesapeake Bay Reduction Fishery Cap and introduce quota periods to distribute removals more evenly over the course of the year. These measures may produce socioeconomic impacts to the commercial reduction fishery and dependent communities as they could limit harvest within the Chesapeake Bay and affect seasonal operations. Additionally, the measures are intended to provide increased ecosystem benefits through enhanced forage opportunities, which could impact individuals who derive value from species that prey upon menhaden.
Two prior socioeconomic studies on the commercial menhaden fisheries provide important context: Kirkely et al. (2011), who assess the economic importance of the reduction sector under alternative harvest scenarios in the Chesapeake Bay, and Whitehead and Harrison (2017), who conducted a socioeconomic study of the commercial bait and reduction fisheries to inform development of Amendment 3. Kirkley et al. (2011) estimated that the reduction sector

supported approximately 519 full- and part-time jobs in Maryland and Virginia, including 347 in Northumberland County, Virginia, associated with total landings of about 141,000 metric tons, of which roughly 85,000 metric tons were harvested from the Chesapeake Bay. Under an extreme scenario in which no harvest was allowed in the Bay and effort could not be shifted to coastal waters, employment losses in Northumberland County were estimated at up to 176 jobs, including 98 direct losses in the reduction sector. The analysis also indicated that a reduction of 1,000 metric tons in Chesapeake Bay quota corresponded to an estimated loss of approximately $630,000 in regional economic output (~$940,000 in 2025) and 3.7 total jobs, including 2.1 direct jobs in the reduction sector. Whitehead and Harrison (2017) applied a similar modeling framework to evaluate economic impacts associated with coastwide quota changes and found a 6.45% increase in total quota (≈12,100 metric tons) would result in combined impacts from the bait and reduction sectors of approximately $6.3 million in economic output and 99 jobs, corresponding to about $520,000 in regional economic output (~$680,000 in 2025) and 8.2 jobs per 1,000 metric tons. Both studies use Leontief input-output models, which do not account for market adjustments or adaptive industry behavior and may overstate long-term employment effects of quota changes.

While neither Kirkley et al. (2011) nor Whitehead and Harrison (2017) explicitly evaluate seasonal harvest restrictions within Chesapeake Bay, both studies suggest that economic impacts are driven primarily by total landings rather than the timing of harvest. Evidence that effort and harvest respond flexibly to economic and regulatory conditions implies that seasonal limits may reallocate fishing activity across the season with limited overall economic impact, provided that total allowable harvest is not substantially reduced. However, impacts may arise if seasonal restrictions constrain periods of high catch efficiency or limit the ability of the reduction sector to maintain consistent processing throughput. It is likely that economic impacts and employment effects associated with output reductions in the reduction sector would respond non-linearly and be characterized by threshold triggers due to high fixed costs in the industry. This would suggest that there are critical output levels, past which employment could change dramatically.

3. PROPOSED MANAGEMENT PROGRAM

This draft addendum considers modifying the Chesapeake Bay Reduction Fishery Cap component of the management program. The intent of the Bay Cap is to limit the amount of reduction fishery harvest that occurs in Chesapeake Bay, a critical nursery area for Atlantic menhaden. Harvest for reduction purposes shall be prohibited within Chesapeake Bay when 100% of the Bay Cap is harvested from Chesapeake Bay, which is defined as areas shoreward of the Chesapeake Bay Bridge Tunnel. Harvest above the Bay Cap in any given year will be deducted from the next year's Bay Cap. Furthermore, unused quota from a region or state cannot be transferred to the Bay Cap to reduce an overage. If the Bay Cap is underharvested, the un-landed fish under the Bay Cap cannot be rolled over into the subsequent year.

An objective is listed for each component to guide evaluation of proposed options in addressing the issues identified for each component in the statement of the problem. When the Board takes final action on the addendum, there will be the opportunity to select any measure within the range of options that went out for public comment, including combining options across issues, unless otherwise specified.

3.1 Chesapeake Bay Reduction Fishery Cap Amount

These options consider reducing the amount of the Chesapeake Bay Reduction Fishery Cap as a precautionary measure in response to concerns about reduced menhaden availability in Chesapeake Bay and consider changes to the manner in which the Bay Cap is set to be more responsive to changes in the TAC. Only one option among Option A, B, and C can be selected. In Options B and C, the Board may select any measure within the range of options. In Option C, a sub-option must be selected from both C1 and C2. Additionally, changes to the Bay Cap do not affect state allocations. Landings that apply to the Bay Cap also apply to Virginia's state allocation.

Option A. Status Quo. The Chesapeake Bay Reduction Fishery Cap is maintained at 51,000 mt. This value represents an approximation of the five-year average of reduction harvest from Chesapeake Bay between 2012 and 2016. An approximate value is used because reduction landings in Chesapeake Bay are confidential. Future changes to the Bay Cap may only be made through adaptive management (i.e., an amendment or addendum).

Option B. One-time Reduction in the Bay Cap. The Chesapeake Bay Reduction Fishery Cap is reduced by a percentage. The Board may select to phase-in the reduction over multiple years. Future changes to the Bay Cap may only be made through adaptive management (i.e., an amendment or addendum).

Sub Option B1: 10% reduction, resulting in a Bay Cap of 45,900 mt

Sub Option B2: 20% reduction, resulting in a Bay Cap of 40,800 mt

Sub Option B3: 30% reduction, resulting in a Bay Cap of 35,700 mt
Sub Option B4: 50% reduction, resulting in a Bay Cap of 25,500 mt
Option B2 applies the same percent reduction to the Bay Cap as was adopted by the Atlantic Menhaden Board for the 2026 TAC. Option B1 applies a smaller percent reduction to the Bay Cap than adopted for the 2026 TAC while Options B3 and B4 apply greater percent reductions; this range accounts for uncertainty in how the abundance in the Chesapeake Bay correlates to abundance of the coastwide stock. The range of options also provides flexibility for the Board to adjust the Bay Cap in response to how it sets the TAC for the next two to three years, as is scheduled to occur at the November 2026 ASMFC Meeting before taking final action on this addendum.

Option C. Linking the Bay Cap to Coastwide TAC

The Chesapeake Bay Reduction Fishery Cap would be set as a proportion of the TAC. In addition, an upper and lower limit would control how low and high the Bay Cap could shift with changing TACs. Setting the Bay Cap as a proportion of the TAC means that any future change to the TAC is also applied to the Bay Cap as the same percent reduction or increase (unless restricted by an upper or lower limit), thus establishing a direct link between the Bay Cap and the TAC. Adaptive management would be required to modify or depart from the automatic Bay Cap setting process selected under this option.

The option considers a range of Bay Cap:TAC proportions, from the current (2026) proportion to the proportions that would result if the Bay Cap were reduced by 10 to 50% relative to the 2026 TAC (Table 2). This range effectively allows the Board to apply a reduction to the Bay Cap similar to that in Option B before locking in the proportion that would maintain the relationship between the Bay Cap and TAC moving forward. Table 2 provides the Bay Cap that would result in 2027 under a status quo TAC scenario; if the TAC were adjusted for 2027, the Bay Cap would change by the same percent (as the TAC from 2026) from the amount shown. For example, the proportion in Option C1c is the same as if the Bay Cap had been reduced by 20% with the 2026 TAC. For a full history of Bay Caps and TACs see Table 1 in Section 2.2.2. Option C also considers upper and lower limits for the Bay Cap (Table 3). The upper limit options range from the highest to the lowest Bay Cap implemented by management. The lower limits range from none to the lower 95% confidence interval of the mean harvest from 2012-2016. This time period is the one used to calculate the current Bay Cap and incorporates the variability around the harvest when the Bay Cap was set at a higher level than the current Bay Cap.

Table 2. Sub-Options C1a-e for setting the Bay Cap as a Proportion of the TAC. Note: Proportions shown here are rounded for clarity; the Bay Cap would be based on unrounded values.

Option	Proportion Basis	Cap in 2027 under status quo TAC (186,840 mt)
C1a	27.3%	2026 Bay Cap : 2026 TAC 51,000 mt
C1b	24.6%	10% reduction to 2026 Bay Cap : 2026 TAC 45,900 mt
C1c	21.8%	20% reduction to 2026 Bay Cap : 2026 TAC 40,800 mt
C1d	19.1%	30% reduction to 2026 Bay Cap : 2026 TAC 35,700 mt
C1e	13.6%	50% reduction to 2026 Bay Cap : 2026 TAC 25,500 mt

Table 3. Sub-Options C2a-e for setting an Upper and Lower limit for the Bay Cap.

Option	Upper Limit	Lower Limit	Basis
C2a.	51,000 mt	None	Upper: Current Bay Cap Lower: n/a
C2b	51,000 mt	25,500 mt	Upper: Current Bay Cap Lower: Maximum Reduction Under Consideration
C2c.	87,216 mt	None	Upper: Highest Cap since management with TAC Lower: n/a
C2d.	87,216 mt	25,500 mt	Upper: Highest Cap since management with TAC Lower: Maximum Reduction Under Consideration
C2e.	75,000 mt	29,000 mt	Upper/Lower: Approximate 95% confidence intervals around the approximate 2012-2016 mean Chesapeake Bay reduction harvest. Note: if Sub-Option C1e is selected, the lower limit for this option will be 25,500 mt.

3.2 Chesapeake Bay Cap Distribution

3.2.1. Quota Periods

These options consider dividing the Bay Cap into quota periods to moderate reduction fishery landings in the beginning and middle of the reduction fishery season as a precautionary measure to support the availability of menhaden to other fisheries and predators.

Option A. Status Quo

The Bay Cap remains an annual measure only with no division into quota periods.

Option B. Three Quota Periods

The Bay Cap would be divided into three quota periods defined by one of the sub-options in Table 4.

Table 4. Options to divide the Bay Cap into three quota periods. Note: Because the reduction fishery begins the first Monday in May and ends on the third Friday in November, depending on the year, the length of the fishing season is either 28 weeks and 5 days or 27 weeks and 5 days. The table outlines the length of each quota period for a season of 28 weeks and 5 days. For years with 27 weeks and 5 days, one week is removed from the final quota period. Example dates are given for 2027.

Option	Description	Length of Quota Periods	2027 Time of Year Example*	Percent of total Bay Cap
B1	Even Length & Even Harvest	9 weeks	May 3–Jul 4	33%
		10 weeks	Jul 5–Sep 12	33%
		9 weeks and 5 days	Sep 13–Nov 19	34%
B2	Even Length & Uneven Harvest	9 weeks	May 3–Jul 4	25%
		10 weeks	Jul 5–Sep 12	25%
		9 weeks and 5 days	Sep 13–Nov 19	50%
B3	Uneven Length & Even Harvest	11 weeks	May 3–Jul 18	33%
		6 weeks	Jul 19–Aug 29	33%
		11 weeks and 5 days	Aug 30–Nov 19	34%

Options B1 and B2 contain three quota periods of roughly equal length, with Option B1 intended to provide an equal distribution of harvest whereas Option B2 gives greater emphasis on delaying harvest until later in the season. Option B3 presents three periods of unequal length, with the extended first period intended to delay some reduction harvest until later in the year compared to recent performance and the short middle period intended to allow the fishery to continue to operate as it has been during what has been the peak period in recent years.

To help understand how Options B1-B3 may alter the reduction fishery's operation, Table 5 provides the 2018–2024 average percent of reduction fishery effort and landings that occurred

in the proposed quota periods. Furthermore, Figure 10 contrasts the options' projected reduction fishery cumulative harvest by week with the 2018–2024 average cumulative harvest by week for the reduction fishery and the Maryland, Virginia, and PRFC pound net fisheries.

Table 5. Approximate average percent purse seine reduction landings and effort in the Chesapeake Bay 2018-2024 corresponding to the quota periods as presented in Options B1-B3.

Option	Length of Quota Period	2027 Dates	Average % Landings (2018-2024)	Average % Effort (2018-2024)
B1/B2	9 weeks	May 3 - July 4	30%	39%
	10 weeks	July 5 - Sept 12	54%	48%
	9 weeks + 5 days	Sept 13 - Nov 19	16%	13%
B3	11 weeks	May 3 - July 18	38%	44%
	6 weeks	July 19 - Aug 29	36%	34%

11 weeks + 5 days Aug 30 - Nov 19 26% 22%

The hypothetical projections of Options B1-B3 assume that weekly harvest is consistent within each quota period.

3.2.2 Quota Period Overages and Underages

Note: This section is only required if Option B is selected above in section 3.2.1 to implement quota periods.

The following options outline how overages and underages within quota periods would be addressed. Without any overage payback provision, there would be little incentive for industry to abide by the in-year quota periods. Without any underage rollover provision, the quota periods may inhibit industry's ability to harvest the Bay Cap.

Option A. No payback for quota period overages with rollover of unused quota within a fishing year.

There would be no payback for exceeding the allocation of a quota period unless it causes the Bay Cap to be exceeded. An overage of the total Bay Cap would be deducted from the following year's total Bay Cap before it is allocated into the quota periods. Any underage of Quota Period 1 or 2 can be used in any subsequent quota period within the year.

Example: A three-quota period split was selected with allocations of 25%/25%/50%. The total Bay Cap is set at a fixed 20,000 pounds, resulting in period allocations of 5,000/5,000/10,000 pounds.

• If the fishery catches 7,000/3,000/10,000 pounds (i.e., a Period 1 overage with no Bay Cap overage), then the following year allocations will remain 5,000/5,000/10,000 pounds.

• If the fishery catches 7,000/5,000/10,000 pounds (i.e., a Period 1 overage and Bay Cap overage of 2,000 pounds), then the following year the Bay Cap would be reduced by 2,000 pounds and then allocated to the periods as 4,500/4,500/9,000 pounds.

• If the fishery catches 5,000/3,000/12,000 pounds (i.e., a Period 2 underage rolled into and harvested in Period 3 without exceeding the total Bay Cap), then the following year allocations will remain the same. A Period 2 underage could only be harvested in Period 3 whereas a Period 1 underage could be harvested in Period 2 and/or 3.

Option B. Quota period overage payback with rollover of unused quota within a fishing year.

Any underage of Quota Periods 1 or 2 would be rolled into Period 3 of the same fishing year. Any underage in Quota Period 3 would not be reallocated.

Quota Period 1 or 2 overages would be deducted from the same quota period in the following year and that poundage would be redistributed to Quota Period 3. If a Quota Period 1 or 2 overage also results in a Bay Cap overage, the Bay Cap overage would be accounted for prior to the Quota Period overage. A Quota Period 3 overage would always also result in a Bay Cap overage (due to the underage rollover provision); when this occurs, the Bay Cap overage would be deducted from the Bay Cap in the following year.

If an overage in Quota Period 1 or 2 cannot be paid back in full by the subsequent year's Quota Period allocation, the remainder of the overage will be subtracted from the next earliest quota period (if available). If that quota period allocation is insufficient, the remaining balance would be deducted from the subsequent quota period. Quota period overages that cannot be paid back in full by one quota period will be accounted for last should there be overages of multiple quota periods.

Underage Sub Option 1. Rather than an underage in Quota Period 1 being rolled over entirely to Quota Period 3, an underage in Quota Period 1 would be rolled over in equal halves to Quota Periods 2 and 3. (An underage in Quota Period 2 would still be rolled over entirely to Quota Period 3.)

Example: A three-quota period split was selected with allocations of 25%/25%/50%. The total Bay Cap is set at a fixed 20,000 pounds, resulting in period allocations of 5,000/5,000/10,000 pounds.

• If the fishery catches 7,000/3,000/10,000 pounds (i.e., a Period 1 overage with no Bay Cap overage), then the following year, Period 1 would be reduced by 2,000 pounds and Period 3 would be increased by 2,000 pounds, resulting in allocations of 3,000/5,000/12,000 pounds.

• If the fishery catches 5,000/3,000/12,000 pounds (i.e., a Period 3 overage with no Bay Cap overage), then the allocations remain unchanged the following year at 5,000/5,000/10,000 pounds.

• If the fishery catches 7,000/5,000/10,000 pounds (i.e., a Period 1 overage and Bay Cap overage of 2,000 pounds), then the following year the Bay Cap would be reduced by 2,000 pounds resulting in baseline period allocations of 4,500/4,500/9,000 pounds. Then, the Period 1 overage would be deducted from Period 1 and redistributed to Period 3, resulting in final period allocations of 2,500/4,500/11,000 pounds.

• If the fishery catches 5,000/5,000/12,000 pounds (i.e., a Period 3 overage and Bay Cap overage), then the following year the Bay Cap would be reduced by 2,000 pounds resulting in baseline and final period allocations of 4,500/4,500/9,000 pounds.

• If the fishery catches 1,000/12,000/7,000 pounds (i.e., a Period 2 overage of 7,000 pounds that cannot be paid back in full by Period 2 the following year and no Bay Cap overage), then the following year Period 2 would be set at zero, 2,000 pounds would be deducted from Period 1, and 7,000 pounds would be redistributed to Period 3, resulting in period allocations of 3,000/0/17,000 pounds.

• If the fishery catches 3,000 pounds in Period 1, the 2,000-pound underage is applied entirely to Period 3 that year resulting in Period 2 and 3 allocations of 5,000 and 12,000 pounds, unless Underage Sub-option 1 is selected in which case the 2,000-pound Period 1 underage is applied in equal amounts to Periods 2 and 3 that year resulting in Period 2 and 3 allocations of 6,000 and 11,000 pounds.

• If the fishery catches 6,000/12,000/2,000 pounds (i.e. a Period 1 overage of 1,000 pounds and a Period 2 overage of 7,000 pounds that cannot be paid back in full by Period 2 the following year and no Bay Cap overage), then the following year Period 1

would first be reduced to 4,000 pounds, then the Period 2 overage would be applied to set Period 2 to zero, the remaining 2,000 pounds would be deducted from Period 1, and 8,000 pounds would be redistributed to Period 3, resulting in allocations of 2,000/0/18,000 pounds.

3.3 Chesapeake Bay Reduction Fishery Cap Revisit Provision

These options consider setting a timeframe for the Board to revisit the Chesapeake Bay Reduction Fishery Cap periodically due to the uncertainty of menhaden's status in the Bay and ongoing work to develop a scientifically-based Bay Cap. Revisiting the Bay Cap does not require the Board to initiate an action to consider changes to the Bay Cap. In either option, the Bay Cap can be reconsidered at any time through the adaptive management process (i.e., an addendum or amendment). A similar revisit provision exists for the quota allocations (every three years).

Option A. Status Quo. There is no set timeframe for the Board to revisit the Bay Cap.

Option B. Revisit Provision. The Chesapeake Bay Cap will be revisited every three years following implementation of this draft addendum.

4. COMPLIANCE SCHEDULE

The Atlantic Menhaden Management Board would need to determine a compliance schedule when considering approval of the draft Addendum.

I have been fishing, crabbing and hunting on the Bay since 1954. My (anecdotal - though extensive) observation is that a 50% cap on menhaden harvest is too little, too late.

I am writing in support of Draft Addendum II. The Chesapeake This is a crucial measure that will help address the localized depletion of menhaden on the Chesapeake Bay and other parts of the East Coast. Atlantic menhaden are a keystone species and declines in their populations have far reaching effects that will be difficult to reverse if left unchecked. More drastic action in the form of a moratorium is needed for the next few years, and other environmental issues need addressed as well. But this measure is an important step.

Comment

Atlantic menhaden are the most important fish in the sea. They are an essential component of the ecosystem and without the menhaden many other species face a collapse including humpback whales, striped bass and even birds. For example, Stockton University reveals an 85% Osprey chick mortality rate in southern New Jersey ospreys due to a severe shortage of Atlantic menhaden. https://www.nbcphiladelphia.com/news/local/skin-and-bones-osprey-chicks-struggle-to-survive-along-jersey-shore/4463737/. There should be an absolute moratorium on large-scale commercial, industrial fishing (or large-scale reduction fishing) of the menhaden until the population is restored. Omega Protein, a foreign-owned company, is responsible for taking 70% of the menhaden catch and this is having catastrophic effects on our ecosystem here which is affecting wildlife and local fishermen. This prioritization of Omega Protein's interests needs to stop. Please protect the menhaden. If a moratorium is not considered, then there should immediately be a cut to the coastwide harvest by at least 55 percent while also beginning the process to give menhaden additional protections urgently needed in the Chesapeake Bay.

I support draft addendum I in the following manner:
Support 3.1 option B4 50% reduction, resulting in a Bay cap of 25,509 mt
Oppose option C linking the Bay cap to coastwide TAC
Support 3.2.1 B1 even length & uneven harvest 5/3-7/4 33%; 7/5-9/12 33%; 9/13-11/19 34%.
Support Option B any underage quota periods 1 or 2 would be rolled into Period 3 of the same fishing year. Any underage in quota3 would not be reallocated.
Support 3.3 Option B the bay cap will be revisited every 3 years

I am in support of Draft Addendum II and do not believe there is any other answer than greatly slowing down the commercial fishing of menhaden. Osprey populations were finally on the rise and now we are seeing a decline all over again. When will we learn and start fighting for biodiversity and the health of ecosystems that we love so dearly? We should start at 50% reductions, the highest rate allowed under this addendum, as soon as we can so these creatures have a fighting chance on our lands.

Comment

My name is Matti Caffiero, and I am currently a senior at the Marine Academy of Science and Technology on Sandy Hook in New Jersey. This past summer, as part of my research capstone project, I observed and collected data on five osprey nests along the New Jersey coast. I took data on the amount and type of fish that ospreys brought back to the nest, and the number of young in the nest. I then correlated this data with the reproduction and fledging rates of the young. After observing all summer, ospreys' young have faced an incredible, devastating breeding season with an 85% loss of chicks across nests on the NJ coast. Doing additional research, I've discovered that this isn't just a NJ coast trend. We are seeing declining osprey breeding rates all across the East Coast. Before starting my data this summer, I read a few short articles on the initial effects of reduced Atlantic Menhaden and the effects this has on ospreys. After this summer, Atlantic Menhaden have been proven to have an incredible effect on ospreys, causing food stress and reduced reproduction rates. The osprey population will continue to decline if nothing is done about Menhaden harvesting. Limiting the Bay Cap to allow the Menhaden population to recover is necessary to support other forms of life. After witnessing the disastrous summer for Ospreys, the only possible way to help reduce the food stress they are experiencing is by saving the Atlantic Menhaden first.

Comment

Atlantic menhaden are a small forage fish, but their importance to the Atlantic coastal ecosystem is enormous. They serve as a critical food source for striped bass, bluefish, weakfish, tuna, sharks, whales, dolphins, osprey, eagles, and numerous other species. They are also an important component of the broader marine food web.

When menhaden populations are heavily harvested, the consequences can extend far beyond the fishery itself. Removing large quantities of this forage fish can reduce the availability of food for predators and place additional pressure on already-stressed fish and wildlife populations. It can also affect recreational fishing, commercial fisheries, whale and bird populations, and the coastal communities whose economies depend on a healthy marine ecosystem.

There is also an important distinction between managing menhaden as an individual commercial resource and managing them as a foundational part of the ecosystem. The value of menhaden should not be measured solely by the market value of the fish that are harvested. Their ecological value as food for other species is considerably broader.

I am asking for the implementation of a precautionary, ecosystem-based approach to menhaden management. That should include:

Maintaining sufficient menhaden abundance to support the predators and ecosystems that depend upon them.

Using the best available scientific data when establishing harvest limits.
Considering the needs of recreational and commercial fisheries, not simply the interests of the menhaden reduction fishery.
Strengthening monitoring and enforcement to ensure that established harvest limits are actually followed.
Evaluating the cumulative ecological effects of large-scale menhaden removals.
Giving serious consideration to regional depletion, rather than relying exclusively on coastwide population estimates.
Continuing to improve management measures as new scientific information becomes available.

This is not an argument against responsible commercial fishing. It is an argument for recognizing that menhaden are much more than a commodity. They are a critical link between the productivity of the ocean and the species—and people—that depend upon it.

Once a forage-fish population is depleted, rebuilding the broader ecosystem can take considerably longer than reducing the harvest in the first place. Preventing that situation is both scientifically prudent and economically responsible.

I respectfully ask the Committee to ensure that Atlantic menhaden management places the long-term health of the marine ecosystem, recreational fisheries, commercial fisheries, and coastal communities at the center of its decisions.

Thank you for your consideration.

Ospreys nests are failing at an alarming rate. Missing pods of Bunker more and more each year. It's not cyclical, it's an issue. Do what's right, preserve the coast and all ecosystems that rely on them. I've watched ospreys nest for the last decade, and the diet has completely switched. 10+ nests that I monitor are within 1 mile of the ocean. They have always returned with bunker. Day in day out. They are now returning with catfish and short fluke and it is far less often. Chicks are starving and something is off.

The health of the Chesapeake Bay and the coastal tributaries is in turmoil. This is evidenced in the declining osprey populations, which is a result of menhaden being overfished. Menhaden are a crucial part of the food web and overall health of our inshore and offshore waters, supporting the populations of numerous species including ospreys, bald eagles, dolphins, whales and so much more. There absolutely 100% needs to be a cap on the amount of menhaden that is allowed to be harvested. The health of the Bay and of our coastal waters is at risk and has been at risk for a long time now, so please make the right decision and approve this addendum!

My understanding is that menhaden are crucial to ospreys and other valuable members of the entire East Coast ecosystem. And that the depletion of this fish is already causing real damage. We need to prevent intentional and accidental destruction of menhaden because they play such a vital part of the whole fabric of wildlife.

The osprey is a glorious American bird. And it's not the only creature starving for lack of menhaden or disrupted by their depletion.

As a rower in the back bays of Atlantic County, Nj for most of my life (over 50 years), in recent years there has been an obvious decline in ospreys on the nesting perches here. We used to marvel at the baby ospreys peering out of the nests. Please limit the menhaden catches or better yet, place a moratorium on menhaden fishing so the ospreys don't continue down this already horrific spiral.

Thank you for the opportunity to comment on the future management of Atlantic menhaden. I am writing in support of protecting ospreys and the broader coastal ecosystem by taking meaningful action to prevent localized depletion of menhaden. As someone who has spent years bird watching and observing ospreys along the New Jersey coast, it appears there has been a disturbing increase in food stress in recent years. This is not simply a matter of fewer chicks surviving. We are seeing adults struggle to find enough prey to support their broods, females returning from migration and failing to lay eggs, adults spending longer periods away from nests searching for food, and chicks becoming emaciated and, in some cases, starving to death. The numbers are deeply concerning. From the research I have come across, in 2025 and 2026, approximately 51% of active osprey nests failed—more than twice the average failure rate of the preceding decade. Only 5% of pairs produced three young, compared with a ten-year average of 22%.

This deserves our attention. Menhaden are not merely a commercial commodity. They are foundational forage fish that transfer energy throughout the coastal food web. Ospreys are particularly valuable indicators because they make changes in prey availability visible. Menhaden support an extraordinary range of marine and coastal wildlife, including ospreys, eagles, gannets, loons, tuna, bluefish, striped bass, dolphins, and whales. They also filter coastal waters and provide food for predators at multiple stages of their lives. This is why I believe localized depletion deserves particular attention.

I am not suggesting that every osprey nest failure has a single cause. Predation, weather, habitat conditions, disease,

contamination, climate-related changes, and other factors can all affect reproductive success. But that uncertainty is precisely why a precautionary approach is warranted. A responsible course of action is to protect the forage base while we continue gathering better data.

I therefore urge the Atlantic States Marine Fisheries Commission to adopt strong precautionary measures in Draft Addendum II to address localized depletion of Atlantic menhaden, particularly in areas where ecological indicators demonstrate that forage availability may be inadequate. Ospreys cannot tell us exactly what is happening beneath the surface. But they can show us when something is wrong.
When young ospreys are starving, we should listen.

Thank you for considering this comment.

You must do something to stop overfishing these waters. The current policies are starving out the osprey. Please ban overfishing in these waters and give the birds a chance to recover. At this rate, these birds are going to become nonexistent in the area. This should be an AGGRESSIVE plan for their recovery.

Stop the unregulated harvesting of food fish that our wildlife, particularly Osprey,, depend on, not only for just their health but especially for their young. More young Osprey's were hatched, only to starve due to a lack of food fish. This is 100% due to over harvesting the fish they depend on. This needs to stop now, before it goes any further.

It is clear that our resident osprey population is suffering greatly from the over harvesting of Atlantic Menhaden. The ASMFC has a responsibility to manage fish populations responsibly, and in its own admission, has indicated that they made a mistake by opening up the Atlantic Menhaden harvest to the level they previously did. It is now time, even beyond the time , to pull back the reigns on the gross overfishing of this species before not only the osprey population crashes, but the complete failure of a number of species in the littoral zone crashes as well. It is now time to restrict the harvest by a full 50%, if not closing the harvest altogether.

Dear Members of the Atlantic Menhaden Management Board,

As a recreational angler, I support reducing the Chesapeake Bay reduction fishery cap by the full 50% considered under Draft Addendum II and establishing quota periods to spread harvest throughout the season.

Protecting menhaden is an investment in the health of our fisheries and the economic future of small shore communities. Menhaden provide food for striped bass and other fish that attract recreational anglers. Reliable fishing opportunities help bring visitors to coastal towns, where their spending supports local jobs and small businesses.

The economic benefits of recreational fishing extend far beyond the boat. Charter captains depend on customers booking trips. Tackle shops, marinas, bait dealers, and boat repair businesses depend on active fisheries. Visiting anglers also spend money at restaurants, hotels, rental properties, gas stations, and other local businesses. In small shore towns, this tourism income helps sustain families and creates opportunities for economic growth.

When fishing opportunities decline, the effects can reach the entire community. Fewer charter bookings and fishing trips can mean less business for shops, restaurants, and lodging providers. Maintaining a dependable forage base should therefore be considered part of protecting the local economies that rely on recreational fishing.

I recognize that the commercial reduction fishery also supports livelihoods. However, management decisions should fully account for the economic value menhaden provide while remaining in the water, including their role in supporting recreational fisheries and coastal tourism.

I urge the Board to adopt the full 50% reduction, establish seasonal quota periods, and monitor forage availability within the Bay. Taking a precautionary approach now can help protect fishing opportunities, small businesses, and the long-term prosperity of our shore communities.

Thank you for considering my comment.

In a time when this country is reeling back regulations, conservation efforts, and laws in place to protect this beautiful country's environment and fragile species, New Jersey and Delaware should be setting an example for the opposite. By protecting our coastal waters from species depletion through overfishing we are protecting the vital coastal species of our states. Reducing the menhaden cap would do just that. There are plenty of alternatives to menhaden with far less detrimental environmental impacts. We know the problem, we know the solution - reduce the cap and let this beautiful and diverse ecosystem thrive as it should.

I support reducing the Chesapeake Bay reduction fishery cap as proposed in Draft Addendum II. A lower cap, coupled with measures to distribute harvest more evenly, would help address the concentration of reduciton fishing effort for other Bay fisheries and the ecosystem, including Bunker and Osprey numbers. ASMFC has identified declining concentrations of Bunker affecting other fisheries such as Stripers and even flounders. Save the wildlife!

The menhaden fishery needs to be managed and controlled to a higher degree.

New Jersey passed a landmark bill in 2002 banning the industrial harvest of menhaden from state waters. We want to protect the health of the resource and all of the ecosystems that benefit from this food source. The waters also need to be protected from foreign fisheries as well.!!

Back in the 1960s, I remember it was rare to an Osprey, this was due to the use of DDT, after that was banned, the Osprey made a full comeback. They are magnificent birds! I find it inconceivable that now…their population is being exterminated rapidly because of the overfishing of the maidenhead fish and that it is being allowed to continue. It is animal cruelty to systematically deprive the Osprey of their prime food source and starving their chicks. I feel absolutely helpless watching this atrocity unfold . Please please stop the fishing fleets from emptying the waters of the maidenhead before it's too late!!!!!!!

Protecting our wildlife must be the top priority. Wr are destroying habitat and driving species toward extinction at a terrifying rate for nothing more than greed.

Osprey are a key ecological indicator species and they are clearly starving for lack of prey like menhaden. Nest failures have doubled in recent years with nestlings becoming emaciated and dying.

Reduce fishing by 50% or better yet more -- a complete moratorium would be best. The ongoing collapse of populations will doom the livelihood of fishermen right along with wildlife, if drastic action isn't immediately taken.

PROTECT OUR WATERS AND WILDLIFE.

I support the most restrictive limits on menhaden commercial harvest. These fish are critical forage for all manner of marine life and are a keystone species to the ecosystem across the East Coast. The need to conserve menhaden is particularly critical at this time due to declining stocks of other forge species.

As a coastal New Jersey resident, it is heartbreaking to see young ospreys starving and nests failing. Menhaden are a critical part of our coastal ecosystem and a vital food source for ospreys and so many other species.

Please protect this essential resource. I strongly support Draft Addendum II and action to prevent localized depletion of menhaden.

Living on the Chesapeake Bay, my husband and I see firsthand what Omega (out of Canada!) is doing to the Osprey and many other predatory birds that need Menhaden to survive. We see firsthand when Omega has “a spill” and our beach is covered with countless species of dead, rotting fish and other sea life that get caught up in their nets. We hear and see the helicopters (spotters) overhead and everyone here on the Bay cringes, because we know that we are helpless to stop such destruction; such shameless pillaging of our beautiful Bay’s necessary resources because money is the driving factor. Money for the Omega coffers and money going into politicians’ greedy hands. We beg you; we plead to you, please stop this. Please stop this destruction of the God given resources needed to sustain the creatures that will not survive this attack.

Subject: Public Comment: Atlantic Menhaden Draft Addendum II

To: comments@asmfc.org

Dear Mr. Boyle and Members of the Commission,

I am writing to urge the Atlantic States Marine Fisheries Commission to take immediate, strong action to protect the Chesapeake Bay ecosystem by implementing strict catch limits under Atlantic Menhaden Draft Addendum II. Specifically, I support options that substantially lower the reduction fishing allowance in the Bay.

As a resident/supporter of the Chesapeake Bay region, I am deeply alarmed by the unprecedented breeding failures and starvation currently devastating our local osprey populations. Decades of scientific monitoring show a direct link between the lack of mature Atlantic menhaden and the inability of ospreys to successfully raise their chicks. We own an osprey platform on our property and have watched year after year the sad demise of osprey chicks. Almost 15 years ago we moved to our location on the water and have watched our mating pair fledge two or three chicks, and now in recent years, it's been

devastating to see the lack of menhaden brought the nest and chicks dying at more than five weeks old, when typically is a chick is going to die, it's the first three weeks of birth. This year was particularly devastating again for all three chicks to die, and the last chick trying to fledge was too weak to fly and repeatedly kept falling into the water. The chick was so weak at one point and couldn't get back to shore so I kayaked out to lift the chick onto my kayak and brought it back to shore and watched it take its last breath. Each year less and less menhaden are coming to the nest and it's been years since we've had successful fledging. We also monitor osprey at the Chesapeake Bay Environmental Center and sadly, the situation is the same.

Menhaden are the ecological backbone of the Chesapeake Bay. Allowing industrial-scale reduction fishing to deplete this critical forage fish at the expense of ospreys, striped bass, and other native wildlife is unsustainable and unacceptable.

Please prioritize the long-term health of the Bay's ecosystem over short-term commercial harvest by implementing the maximum possible protections in Draft Addendum II. Thank you for your time and consideration of these comments.

Sincerely,
Doris Key, Chester, Maryland

I live in Annapolis, and the Chesapeake Bay is part of my everyday life. The Bay is not just a beautiful backdrop to where I live; it is an ecosystem that I care deeply about and want to see protected for generations to come. Watching ospreys hunt over the water and raise their young is one of the things that makes living on the Chesapeake so special.

Menhaden are not just another fishery resource. They are a critical part of the Chesapeake food web, providing food for ospreys and many other predators. When we remove large numbers of menhaden from the Bay, we need to consider what remains for the wildlife that depends on them.

The ASMFC has recognized concerns about the concentration of menhaden fishing in the Bay and is considering reducing the Chesapeake Bay reduction fishery cap by up to 50%, along with measures to spread harvest more evenly throughout the fishing season.

I urge the Commission to take a precautionary approach.

Protect menhaden during the months when they are most important to Chesapeake wildlife. Avoid concentrating fishing pressure during the spring and summer, when ospreys are nesting and raising their young. Give the ecosystem enough forage to support the predators that depend on it.

We should not wait until there is undeniable evidence of harm before taking action. As someone who lives on the Chesapeake, I believe responsible management means looking at the health of the entire ecosystem, not simply how many fish can be harvested.

Please reduce the Chesapeake Bay reduction fishery cap and implement meaningful seasonal protections to ensure enough menhaden remain in the Bay to support ospreys and the broader Chesapeake ecosystem.

I strongly encourage the ASMF Commission to listen to the American citizens who reside along the Atlantic coast. We are pleading for someone to stop our marine ecosystem from being destroyed by reduction fishing. Anyone who spends their lives on the water have seen the decimation of menhaden stock in the bay firsthand. I am an avid recreational fisherman. There are no bunker in the bay! Years ago you could go snag bunker for crabbing or net peanut bunker for fluking. Those days are long gone. Now if you want to go crabbing with native bait, you have to spend a mint on tiny bunker. The massive schools of menhaden are just a memory! It is a complete disaster and a direct result of out-of-state vessels using aircraft to target the schools and send in a fleet of watercraft to vacuum up all the fish. It should be illegal to harvest fish in this manner and it needs to end before our fishery completely collapses. Our beautiful coastline in New Jersey is a priceless resource for all the life that depend on it. Not to mention recreation & tourism. We need the ASMF & NJDEP to support the strongest Addendum II protections. Not only do the stripped bass and countless other fish depend on menhaden, so to does the Osprey. It is a crying shame what the lack of menhaden is doing to them. I was on Great Bay a couple of weeks ago and watched a pair of Osprey on an empty nest. You could tell they were malnourished and sick. The one flew off for a while and came back with no food. It was exhausted and just layed out on the wood with its wings hanging down. It is disgusting what greed is doing to our marine ecosystem.

I do not believe this goes nearly far enough, but I support...

• Bay Cap Amount: Sub-Option B4 — a 50% reduction, resulting in a 25,500 mt cap.

• Quota Periods: Option B1 — even-length periods with evenly distributed harvest.

• Underage Provision: Underage Sub-Option 1 — roll Period 1 underages evenly into Periods 2 and 3.

• Revisit Provision: Option B — revisit the Bay Cap every three years.

• ASMFC commissioners and NJDEP to support a 2027–2029 coastwide TAC projected to achieve the ERP F target.

I support an end to reduction fishing all up and down the Atlantic coast! Please do what is right for the bay by standing with the American people against these greedy corporations destroying lives! Thank you for your attention to this most important matter. This must be addressed before it is too late

As a wildlife photographer these issues deeply disturb me and should disturb everyone. Many would agree that Menhaden is a keystone species for many aquatic animals and predators. To not consider these animals in our commercial fishing is a disservice to not only the animals that depend on them but the communities that depend on a healthy and biodiverse ocean. I implore you think about your children starving and what you would do to put food back into their mouths and the life changing affects it would have on you. Think of these animals beyond the osprey who can't work, who can't use technology to compete. Protect them like you would protect your voiceless children please and thank you.

As a 40 year resident of the Barnegat Bay Area, I have seen the population of ospreys slowly build due to the heroic efforts of many committed individuals. But it has been heartbreaking to see the collapse of the osprey population over these last two years. We must consider a moratorium on the commercial menhaden fishery immediately. Surely there are other sources of protein available for dog food until the menhaden population and thus the osprey population are allowed to rebound. If the fishery is managed sensibly, it will be good for the fishermen as well as the ospreys.

I have been fishing in the Barnegat bay and offshore of Ibi for about 24 years. I have never seen so many osprey abandon their nests early in the season. The big schools of bunker offshore have disappeared. It will crush local communities if the fishery collapses. Omega protein is wasting a resource that feeds so many. We need an immediate moratorium on industrial bunker fishing.

Our family lives on the headwaters of Mill Creek on the Magothy River, one of the tributaries of the Chesapeake Bay. We have not seen a single osprey this season! This is a frightening, dramatic decrease from years past, when we saw ospreys on a daily basis. I understand that their food source menhaden, has been severely depleted by companies overfishing menhaden to provide Omega 3 for human vitamins. This is writing a death notice for the osprey species. If we do not wish for osprey to become extinct, severe penalties must be levied for overfishing menhaden. Please do not allow the osprey population to become extinct, not on our watch. Take action now. Please, we are counting on you to replenish the osprey population by outlawing overfishing. Sincerely, Lorraine T. Kemp

I strongly urge the Board to reduce the Menhaden harvest cap by the full considered amount of 50%.

As a member of a multi-generation coastal family, we have seen the loss of Menhaden and the broad reaching impacts of their loss that are devastating many levels of the local ecosystem. The bays, once teaming with life, are growing quiet. This level of harvest pressure will take generations of recovery

Balance must be restored and that will require drastic harvest reductions that are vigorously enforced.

Please protect our coasts and our future.

Ospreys act as biological indicators (or "sentinel species") for the health of oceans, bays, and estuaries. Because they are apex predators with a diet consisting of [99% fish](url: cbf.org), their survival, reproductive rates, and biological data directly reflect the ecological conditions of the waters beneath them.
Ospreys act as the ocean's early warning system in three critical ways:
1. Tracking Biomagnification and Pollution
Because ospreys sit at the top of the aquatic food web, they accumulate toxins through a process called biomagnification. Small fish absorb low levels of pollutants, larger fish eat those small fish, and ospreys absorb the concentrated doses from all the fish they consume.
Scientists routinely analyze osprey eggshells, blood, and feathers to monitor chemical trends. Historically, this sent an alarm about the pesticide DDT, which caused osprey eggshells to thin and populations to collapse. Today, researchers track contemporary threats—such as PCBs, heavy metals (like mercury), microplastics, and pharmaceuticals—by studying osprey health.
2. Signaling Commercial Overfishing and Fish Depletion
Ospreys are highly specialized hunters that rely on an abundance of surface-dwelling forage fish, such as Atlantic menhaden. When local fish populations decline due to overfishing or environmental stress, ospreys feel the impact immediately.

Recent studies highlight severe reproductive deficits in coastal areas. For instance, research from the [U.S. Geological Survey (USGS)](url: usgs.gov) underscores how a shortage of menhaden correlates with catastrophic chick starvation and nest failures. An osprey community unable to fledge young is a strong indicator that the underlying marine food web is being depleted.

3. Measuring Habitat Quality and Visibility

Ospreys are visual, shallow-water hunters that cannot dive deeper than about three feet. To successfully catch prey, they require:

• High water clarity: Poor visibility caused by industrial runoff, sediment pollution, or massive algae blooms makes it nearly impossible for them to spot fish.

• Stable weather patterns: An increase in severe climate events can disrupt their hunting ability and compromise nesting structures.

When ospreys abandon historically successful coastal nesting sites, it alerts marine biologists to degrading local water quality long before standard manual testing might catch it.

Saving the ospreys from the current food shortage crisis requires immediate, localized changes to marine policy and fisheries management. The historic lows in breeding success along the Atlantic Coast and Chesapeake Bay are overwhelmingly linked to the scarcity of Atlantic menhaden, their primary, nutrient-rich food source.

Because wild ospreys cannot be easily fed by humans, the only viable solution is to restore their natural food supply. Wildlife advocates, researchers, and policymakers are focusing on the following urgent actions to reverse the crisis:

1. Drastically Lower the Commercial Menhaden Harvest Cap

The most critical battleground is policy management. Industrial "reduction fishing" operations scoop hundreds of millions of pounds of menhaden out of coastal waters annually to process them into fishmeal, pet food, and dietary supplements.

2. Ban or Restrict Purse Seine Fishing in Critical Regions

Even when coastwide menhaden numbers seem stable on paper, intense localized fishing creates "food deserts" in the specific bays and estuaries where ospreys nest.

• Virginia Commitments: Virginia is the only state on the East Coast that still allows industrial reduction purse-seine fishing within its internal waters. A major coalition of conservation groups is pushing state leaders to ban this practice within the Chesapeake Bay entirely.

• Time-Based Restrictions: Forcing commercial fleets to spread their harvest more evenly throughout the year—or halting industrial fishing entirely during the peak osprey breeding months of April, May, and June—would ensure parents can find food when chicks are most vulnerable to starvation.

3. Implementing Ecosystem-Based Fisheries Management

Traditionally, fishing quotas are set based strictly on how many fish a population can lose before the species itself collapses. Conservationists are demanding a shift toward Ecosystem-Based Fisheries Management (EBFM). This system requires managers to calculate exactly how many menhaden are needed to sustain apex predators like ospreys, bald eagles, and whales before allocating quotas to commercial fleets.

4. Enhancing Local Nest Monitoring & Public Advocacy

Public pressure is driving the push for legislative change. Organizations like the Chesapeake Bay Foundation, the American Bird Conservancy, and local initiatives like the New Jersey Osprey Project rely on citizen science to document nest failures. Tracking these failures provides the hard data needed to challenge commercial fishing lobbies in court and regulatory hearings.

The Atlantic Menhaden population should be managed to keep the ecosystem healthy, not the fishing industy economicly rich.

I live part time on the Rappahannock and fish twice a year at Cape Hatteras (spring & fall) and occasionally in the lower Chesapeake Bay, but for the past 3-4 years my group of twelve licensed sport fishermen have caught almost no fish.
I'm very concerned as to what has happened to the fish and when in before years they have been plentiful.
Have the menhaden been reduced as feed for the other game fish. As an 81 year old lifelong fisherman, it is disappointing that the spot, flounder, blues etc have gone elsewhere and sport fishing is no longer productive. I have given my boat away and am disappointed that the fish are gone in both the Chesapeake Bay and Atlantic coastal (Hatteras) area.
Greater limits should be placed on Menhaden fishing and the actual cost benefits for the USA should be scrutinized. It appears that the menhaden depletion is grossly impacting both the sport fishing industry and wild such as the Osprey. We want and need both in America.

Thank you

I am in support of reducing the Chesapeake Bay reduction fishery cap by 50% to preserve the predatory bird species that live along the bay. Meaningful intervention and regulation is needed to save predatory bird species, like the Osprey, and preserve the ecosystem of the Chesapeake Bay.

There is a coastwise need in protecting menhaden all along the coast. As a fisherman I know of the need to protect and build the stock of stripped bass. Obviously their most important forage fish is the menhaden. Also the ospreys are taking a beating up and down the coast. Please protect the coastal environment and reduce the reduction fishery in the Chesapeake

I strongly urge the Board to reduce the Menhaden harvest cap by the full considered amount of 50%.

As a member of a multi-generation coastal family, we have seen the loss of Menhaden and the broad reaching impacts of their loss that are devastating many levels of the local ecosystem. The bays, once teaming with life, are growing quiet. This level of harvest pressure will take generations of recovery

As I understand it, the primary commercial operation unrelentingly harvesting these fish is foreign owned and the bulk of it's production is exported. This seems contrary to the best interests of the Atlantic states this board is supposed to represent.

Balance must be restored and that will require drastic harvest reductions that are vigorously enforced.

The menhaden fishery needs to be managed and controlled to a higher degree.

New Jersey passed a landmark bill in 2002 banning the industrial harvest of menhaden from state waters. We want to protect the health of the resource and all of the ecosystems that benefit from this food source. The waters also need to be protected from foreign fisheries as well.!!

Ospreys are starving due to lack of menhaden. How many other species are being affected? Please stop overfishing the menhaden, especially in VA where commercial boats are still allowed. This has to stop.

When I was a child, I went to aquarium camp and learned about the fight to help Osprey's by banning DDT... It galvanized and reinforced a love for animals and that is something that is a throughline in my life.
Now, as the mother of a 14 month old, I hope my daughter will grow up in a world that protects biodiversity and cherishes the natural splendor we have been gifted enough to share our lives and time with... I hope she will get to go to aquarium camp and learn about how we, once again, made the right decision to save the Osprey.

Please reduce Virginia's 75% share of the quota.

There is limited research done on how much bunker needs to be left in the Chesapeake to sustain the predators that rely on them. Clearly, the current amount they are allowed to harvest is damaging the ecosystem as striped bass, osprey and other predators that rely on them are struggling . So why allow them to keep harvesting massive amounts while it's unclear what the actual sustainable harvest would be? It makes no sense. So many people have fought so hard and spent countless amounts of money trying to save the striped bass and the osprey. We can't let them ruin that. Even just spreading their quota out throughout the year so that there is enough forage during the spawn would help. Something needs to change. I would like my kids to enjoy the same fisheries that I had growing up. Recreational anglers are already working so hard to try and be more sustainable by using single and circle hooks and by practicing catch and release more and more, so why can't the reduction fishery do their part?

I fully support reducing the current menhaden quota by the proposed 50%. This is a good start but Cooke Inc aka Omega Protein should be pushed out of the Chesapeake Bay completely atleast 3 NM off the coast similar to every other state on the east coast. They also should not be able to impede menhaden from entering the Chesapeake Bay. It also should be illegal to use spotter planes, drones, etc for the purpose of spotting menhaden. I hope you make the right decision to save this great natural resource before it's too late and has a lasting negative effect on the Chesapeake Bay ecosystem.

I ask that there be a 50% decrease in the menhaden being fished by the omega fish oil supplement companies. Something needs to be done before it's too late for the osprey and many other environmental issues over fishing creates.

Comments made for the Chesapeake Bay Atlantic Menhaden Comment on Draft Addendum II

“Thank you for the opportunity to speak. My name is Capt. Paul Eidman, commenting from New Jersey — the second-largest harvester of menhaden on the East Coast, and with that comes responsibility.

I am a Jersey-based saltwater fishing guide and the founder of the non-profit group Menhaden Defenders, and I sit on the Jersey Coast Anglers Assoc. board of directors as Forage Fish Chairperson.

For my 3 minutes tonight, I will keep my remarks focused specifically on Draft Addendum II.

The addendum identifies three core issues: (1) the Bay Cap is not linked to the TAC, (2) the Bay Cap does not control when harvest occurs, and (3) the Bay Cap has not been revisited regularly despite major changes in the fishery.

The document makes clear that Chesapeake Bay is a critical nursery area for Atlantic menhaden. It also notes troubling trends in predator species that rely on menhaden — including striped bass, bluefish, weakfish, and spiny dogfish — all showing signs

of stress or decline (Draft Addendum II, p. 2).
